EXPERIMENTS ON CANCER-PRODUCING SUBSTANCES

BY

E. L. KENNAWAY, M.D., D.Sc.

(From the Cancer Hospital Research Institute, London.)

(With Special Plate.)

In a previous paper¹ the production of cancer by a mixture of compounds formed from isoprene

(2 methyl butadiene $\text{CH}_2 = \text{C} - \text{C} = \text{CH}_2$)

at about 820° C. was recorded. In the present paper further experiments on the formation by heat of cancer-producing materials are described. The nine products tested were obtained from the following sources at, approximately, the temperatures* stated: (1) acetylene (700°), (2) acetylene (800-900°), (3) California petroleum (880°), (4) isoprene (700°), (5, 6, and 7) Durham Holmside coal (450°, 560°, and 1,250°), (8) human skin (920°), (9) yeast (920°).

Technique

These substances, with the exception of the coal, were exposed to heat in the manner described in the earlier paper.¹ A silica tube about 36 in. by 1 in. is filled with pieces of porous plate and heated in a gas furnace; the temperature is ascertained by means of a nichrome thermocouple inserted into an inner silica tube which reaches nearly to the middle of the larger one. When the temperature required has been reached, the gas liquid or vapour derived from solid materials is passed through the heated tube and the condensable products collected in water-cooled receivers. Further details are given under "Skin Tar" below. By this method the temperature at the point of the thermocouple is measured very accurately, but it is not possible to control the temperatures to which the vapours may be exposed in all other parts of the tube; hence the temperatures stated in this paper are to be taken as approximate only.

The tarry products were applied twice weekly to mice (generally 100 for each test) in the interscapular region.

ACETYLENE TAR

A compound even simpler than isoprene—namely, acetylene $\text{HC}\equiv\text{CH}$ —can be used as a source of cancer-producing compounds. Berthelot in 1866 showed that a tarry material containing benzene is formed when acetylene is heated; this synthesis of benzene is, of course, of great importance in the history of organic chemistry. He says:

'En chauffant l'acétylène pur, dans une cloche courbe sur le mercure à la température de ramollissement du verre vert, on voit ce gaz diminuer peu à peu de volume. En même temps des produits goudronneux apparaissent. Dans une expérience au bout d'une demi-heure 97 centièmes de l'acétylène primitif avaient disparu 3 centièmes seulement subsistant. Après une suite fastidieuse de manipulations méthodiques j'ai obtenu en quantité suffisante un liquide jaunâtre que j'ai soumis à une distillation fractionnée. J'ai isolé toute une série de carbures d'hydrogène polymères de l'acétylène (benzène, styrène, hydride de naphthalène, hydride d'anthracène, carbures fluorescents, etc.). Le benzène forme près la moitié du produit total.'

Recently Zelinski² has shown that these condensation products of acetylene can be prepared in much greater quantities if the gas is passed through a heated tube filled with wood charcoal, about 70 to 74 per cent. of the acetylene is then converted into "goudron acétylénique." He obtained by this method as much as 180 grams of liquid in eleven hours at 640° to 650°, the compounds identified were benzene, toluene, paraffene, styrol, indene, naphthalene, fluorene, and anthracene.

These "produits goudronneux" of acetylene, discovered by Berthelot sixty years ago, have considerable cancer-producing power (Figs 1 and 2). In the series of experiments described here acetylene, generated in the ordinary way from calcium carbide, was purified by bubbling through watery solutions of (1) copper sulphate and sulphuric acid (two flasks), (2) mercuric chloride and hydrochloric acid, and (3) caustic soda, and then passed into the silica tube. The tube was charged in the earlier experiments with wood charcoal as in Zelinski's method, the charcoal was first extracted with ether to remove any traces of wood tar which might possibly be present. Later it was found that porous plate could be used, and with the latter material stoppage of the tube by deposition of carbon from the gas occurred much less frequently. The tar is a mobile dark brown liquid smelling of benzene, the yield in these experiments was generally not more than 4 or 5 c.c. an hour. Two different products made at 700° and at 800° to 900° respectively were used.

Acetylene Tar (700°)—The two first tumours appeared on the 86th day, the first section showing a malignant growth was obtained on the 153rd day (Fig 1). By the 258th day 15 tumours had been obtained of these, 13 were undoubtedly cancers in which the epithelium reached or penetrated the panniculus carnosus, the other 2 were papillomata with some downgrowth.

Acetylene Tar (800° to 900°)—The first tumour appeared on the 105th day. This tar was certainly less effective than the 700° tar, unfortunately there was a high mortality in the 800° to 900° series which made comparison more difficult. On the 125th day the 700° series consisted of 28 mice, of which 13 bore tumours, and the 800° to 900° series of 14 mice, of which only 2 bore tumours. The experiment was not continued after the 216th day as it was clear that the 800° to 900° tar was inferior to the other, this series of mice, and another pair fed subsequently with tar made at the same temperature, yielded in all 8 cancers and 6 papillomata with downgrowth (Fig 2). Altogether, in these and some other series of mice to be reported later, 30 cancers have been produced with three different preparations of acetylene tar. This acetylene tar resembles isoprene tar in the comparative simplicity of its composition: elements other than carbon and hydrogen can be present in it in traces only. It therefore offers for the study of cancer production a material less complex than coal tar, for in the latter oxygen, nitrogen, and sulphur are present also. The samples of acetylene tar prepared hitherto seem to be less active than isoprene tar (820°) in causing the growth of tumours, but the former has the great advantage of being easier to prepare in quantity. A chemical study of acetylene tar is now in progress in this Institute.

* All temperatures referred to in this paper are on the centigrade scale.

HEATED PETROLEUM
In this experiment a petroleum having no cancer producing power was found to acquire this power when heated

The Californian petroleum used had been tested in the unheated state by Dr. Leitch, and found by him to have no cancer producing action¹, in his experiment 100 mice were used, and although the painting was continued until the 515th day, when the first mouse died, no tumours were obtained. A sample of this oil was then passed at the rate of 12 to 15 ccm an hour over porous plate in the silver tube at about 880° in a current of hydrogen, the product is darker and more viscous than the original oil, and smells of benzene. The first tumour appeared on the 67th day after nineteen applications of this material, the first sections showing malignancy were obtained on the 206th day. The experiment was not continued after the 206th day, when 10 mice, all bearing tumours, remained alive. Altogether 15 tumours were examined microscopically, of these, 11 were certainly malignant, for the downgrowing epithelium reached or penetrated the primum nucleus carnosus, and the remaining 4 were papillomata. The importance of heat in the formation of cancer-producing substances is shown very clearly by this experiment. In the petroleum industry the changes brought about in the oil by heating, including the conversion of aliphatic into aromatic compounds (anthracene, phenanthrene, pyrene, etc.), are well known, and have been the subject of many patents. The experiment shows also that the products of petroleum most dangerous to workmen must be any strongly heated distillation residues, two out of the few fully recorded cases of petroleumi cancer in the literature² occurred in men exposed to such materials.

ISOPRENE TAR (700°)

The isoprene tar described in a previous paper¹ was made by Staudinger, Lindle, and Heiold, who first prepared such material, and found considerable chemical differences between this prepared from isoprene at 700°, and at 800°. At 820°, the former consisted chiefly of unsaturated, the latter chiefly of saturated aromatic compounds. One might expect, then, that a comparison of the cancer-producing power of two such tars would indicate the class of compound which causes the growth of the tumours. Accordingly, an isoprene tar was made at 700° to 720°, the technique being in other respects the same as that of the earlier preparation at 820°. The 700° to 720° tar differed from the 820° tar in being more liquid, and in retaining a faint smell of isoprene, in causing new growth it was certainly inferior. The rates of production of tumours by the two tars are compared in Table I.

TABLE I—*I of Isoprene Tars (700° and 820°)*

	Number of Mice Alive—			Percentage with Tumours
	With Tumours	Without Tumours	Total	
Day 87 Isoprene tar 700°	5	41	46	11
	14	27	41	35
Day 132 Isoprene tar 820°	3	16	19	16
	1	7	8	75
Day 187 Isoprene tar 820°	3	15	18	17
	19	1	20	95

TABLE II—*Tars from Durham Holmside Coal*

known time steps (450° 560° 1250°)
The tar was heated in the Amsterdam gasworks and found that the tar produced cancer more than the tar from the Rotterdam gasworks. The tar from the Rotterdam gasworks was heated at a lower temperature and contained a smaller amount of paraffins and phenol. The tar from the Rotterdam gasworks was heated at a lower temperature and contained a smaller amount of paraffins and phenol. The tar from the Rotterdam gasworks was heated at a lower temperature and contained a smaller amount of paraffins and phenol.

not give quite conclusive results. But it is known that different coals may yield tars differing considerably in chemical composition (see, for instance, Boin ten³), in such experiments it is therefore necessary that the tars compared should be derived from the same sample of coal. Through the kindness of the Fuel Research Board and of the staff of H.M. Fuel Research Station at Greenwich, some material very well fitted to the object in view was obtained—namely three tars made from Durham Holmside coal at 450°, 560°, and 1250°, the list of these would correspond most nearly to the ordinary gasworks tar.

TABLE II—*Tars from Durham Holmside Coal*

Day	450°		560°		1250°	
	With Tumours	Without Tumours	With Tumours	Without Tumours	With Tumours	Without Tumours
138th	1	0	11	55	11	52
178th	4	0	14	30	18	23
230th	2	47	10	19	10	10
290th	5	22	11	6	6	5
373rd	5	6	4	—	2	1

The experiment was stopped on the 373rd day

The results given in the table show that the 450° tar was much inferior to the two others in tumour production. Thus on the 230th day the tumour bearing mice made up 50 per cent of the 1,250° series, 33 per cent of the 560° series, and only 4 per cent of the 450° series. Seven tumours from the 450° mice were examined microscopically, there was little or no downgrowth in six of these in the seventh the epithelium reached the primum nucleus carnosus, and must be regarded as malignant in character. From each of the two other series 6 epitheliomata were obtained, the remaining tumours from these two series being, in all, 15 papillomata, of which 13 showed downgrowth. The comparison of such batches of mice is subject to many sources of error, but this experiment seems to demonstrate (1) that the 450° tar is much less active than the other two, and (2) that the 1,250° tar is somewhat more active than the 560° tar. The results, then, indicate that, when coal is carbonized, (1) the cancer-producing agent is being formed in very small amount even below 450°, (2) a rapid increase in its formation takes place between 450° and 560° and (3) this increase continues, but at a much slower rate from 560° to 1,250°, in other words, the curve expressing the formation of this agent with rising temperature ascends at first very steeply from the region about 450° and proceeds much less steeply from 560° to 1,250°.

TARS DERIVED FROM YEAST AND FROM HUMAN SKIN

Until recently all the cancer producing substances available for experiment have had their origin in more or less remote geological periods, they have been derived from the coal or oil shales of the Carboniferous period, from the Oligocene lignite beds, or from petroleum bearing strata ranging from the Devonian to the Miocene. But is it necessary to go so far back into the past for such materials? The laboratory product isoprene is actually derived, by way of turpentine oil or caraway oil, from plants now living. Experiments were carried out to ascertain whether other plants and animals living at the present day could yield compounds which produce cancer.

The two materials selected for the first experiments were (1) yeast representing the unicellular organisms in which no malignant growth can occur, and (2) human skin, including the epidermis in which cancer may arise naturally.

Skin Tar

Human skin was obtained from amputated breasts and limbs and from the margin of the incision at autopsies, in subjects affected with cancer skin having any appearance of infiltration with the growth was rejected. The skin was freed as far as possible from adipose tissue cut into small pieces and dried in a vacuum desiccator over calcium

100

F 100

chloride. Microscopic sections of such skin before drying show that the epidermis may occupy as little as one fiftieth of the area of the section, all the rest consists of the fibrous tissue of the dermis. Hence it may be that only a very small fraction of the tar obtained from such skin is derived from the epidermis. A current of hydrogen, purified by passing through solutions of potassium permanganate and sulphuric acid, silver nitrate, and caustic soda was passed through a silica tube 36 in. in length, of which the proximal one third was filled with dried skin (about 45 grams) and the distal two thirds with porous plate, the temperature near the middle of this distal portion was read by means of the thermocouple. The temperature was first raised to the degree selected (920° or 780°) and heat was then applied very gently to the proximal portion of the tube containing the skin which was thus decomposed slowly (45 grams of dried skin in six to seven hours) the volatile products passed over the hot porous plate and the condensate (solid ammonium carbonate and carbon watery fluid and tar) was collected in cooled receivers, and subsequently shaken with water and ether. The ethereal layer was shaken twice with water to remove ammonia and a part of the pyridine the ether evaporated in *vacuo*, and the black oily residue was applied to a series of 50 mice twice weekly.

Skin Tar (920°)—The first papilloma appeared on the 93rd day, and the first specimen showing malignant growth microscopically was obtained on the 128th day. On the 183rd day 13 out of the 16 mice alive bore tumours. In all, at the time of writing (233rd day) sections of 4 cancers and of 5 tumours in which the downgrowth reaches, or nearly reaches, the panniculus carnosus, have been obtained, while of the 8 mice alive 5 bear tumours which have the appearance of malignancy (Figs 4 to 9).

[Note added at Correction of Proof—At the present date (June 22nd, 1925) total numbers of tumours produced are

	Cancers	Papillomata
Acetylene tar	36	15
Skin tar (920°)	12	8
Yeast tar (920°)	3	2

These experiments with skin tar seem to be the first in which a cancer-producing material has been obtained by any treatment of human tissues. One cannot, of course, assume that these cancers of the skin produced by a tar derived from skin are in any way more closely allied in origin to the naturally occurring epitheliomata than are cancers produced by a tar derived from the floor of the Coal Age, at the present stage of the investigation one cannot even form any opinion upon this point. However, it is not wholly impossible that the living skin may be capable of forming very slowly substances which, when required in bulk and rapidly, can *in vitro* be produced from skin only at a red heat, many instances are known of the ease with which the body or its enzymes bring about chemical changes which otherwise demand strong reagents or high temperatures—for example, the hydrolysis and oxidation of fats and proteins. In making cancer-producing material from skin we expect to obtain a good supply of it in a few hours, and must hence use very vigorous methods, it is possible that the body at its own temperature takes months or years to produce a quantity of some substance sufficient to influence the growth of a few cells only.

Yeast Tar (920°)

Compressed yeast was treated in exactly the same manner as the human skin, the products in the receivers contained more water and less ammonia than did those from the skin, but the two tars showed no obvious difference. Most unfortunately there was a high death rate among the mice painted with 920° yeast tar, this makes difficult any exact comparison with the tar made from skin at the same temperature, but there is no doubt that the yeast tar was the slower in action. Thus, on the 182nd day, 11 out of the 18 mice in the skin series, and only 1 out of the 9 mice in the yeast series, showed tumours. The first tumour was situated underneath the epidermis, it was noticed on the 178th day, and the mouse was killed four days later. The tumour (Fig 10) was an epithelioma. Sections from another mouse (229th day) showed a tumour with downgrowth approaching the panniculus carnosus. At the time of writing (238th day) 3 out of the original 50 mice are alive, all bear tumours, and of these one is almost certainly malignant.

DISCUSSION

1 It may be said that these pyrogenous materials derived from acetylene, isoprene, petroleum, yeast, and skin produce cancer simply because they are all "irritants", and that the multiplication in the laboratory of instances of "chronic irritation" is not required. To apply thus to a substance, after it has been shown to produce cancer, the term "irritant" gives an appearance of explanation which is illusory, we only know that the substance produces cancer. There seems to be a tendency at the present time to state that a substance such as soot gives rise to cancer because it is an irritant, and at the same time tacitly to regard it as an irritant simply because it gives rise to cancer, thus circular treatment of the matter is of no value at all. Would anyone have thought of singling out soot as an irritant if its carcinogenic power had happened to remain unknown?

Again, the undoubted irritants which do not produce cancer are so numerous that the same term cannot usefully be applied to define the action of other agents, some of them not obviously irritating in character, which do produce cancer. Thus blast-furnace tar, and some petroleumums which give negative results in mice, do far more visible damage to the skin than acetylene tar or isoprene tar. Chlorinated acetylene tar is much more irritating than the original tar, but the carcinogenic power has been greatly reduced. Other irritants which have given negative results on the mouse's skin are acridine, the effect of which on the human skin is well known, and the product obtained by combining ethylene with phenyl magnesium bromide in the presence of nickel chloride. Other instances could be taken from the industrial diseases of the human skin.

It seems, then, that the irritation which causes the growth of cancer must be of a special kind or must act upon some special element in the tissues.

2 No invariable relation has been found between the temperatures at which these various materials are formed and their comparative activity in producing tumours. Thus the three tars made from coal at 450°, 560°, and 1,250° show an ascending order of potency, the 820° isoprene tar is more active than the 700° tar, and experiments still in progress indicate that the 920° skin tar will prove more effectual than the 780° tar. In all these cases the higher temperature gives the more active product. But, on the other hand, in the case of acetylene, a low temperature (700°) gives a product more active than that produced at 800° to 900°, possibly at the latter temperature a larger proportion of the gas is decomposed into carbon and hydrogen. The errors inherent both in the measurement of the temperature to which the substance is exposed, and in the comparison of different series of mice, take effect upon such experiments, and no general conclusion on the influence of temperature can be drawn at present. But the three sets of observations on products from (1) Durham Holmside coal, (2) Californian petroleum, and (3) isoprene, agree in indicating the importance of that range of temperature where the formation of aromatic compounds is known to be in progress.

3 The idea suggests itself that acetylene may be a decomposition product common to coal, mineral oils, yeast, skin and isoprene, and that the cancer-producing material obtained from these very diverse sources is actually formed from acetylene by the synthetic process discovered by Berthelot. One would, then, expect a tar made from acetylene itself to be more active than any other, but this has not proved to be the case. Probably the yield of cancer-producing substance depends largely upon catalytic reactions which cannot as yet be controlled. Further experiments upon products from other tissues and tissue constituents are in progress in this Institute.

SUMMARY

1 Cancer has been produced in mice by substances obtained by heating (1) acetylene, (2) isoprene, (3) yeast, (4) human skin, to temperatures ranging from 700° to 920°. Acetylene is the simplest organic compound from which a carcinogenic material has so far been obtained.

2 A petroleum which produced no tumours of any kind in mice in a prolonged experiment showed very active

A chemical precipitation reaction is described by Kahn ¹⁸ to which class Botche's reaction also belongs ¹⁹. The latter has been shown by me to have little diagnostic value ^o. The rate of sedimentation of red corpuscles has been used for the diagnosis of cancer by Høffgaard ¹.

The flocculation method was first used by Weil and Braun ². They noted the flocculating power of cancer scrums upon leathin solution in 17 cases. During the course of this work Roffo ²³ has published a flocculation reaction for the diagnosis of malignant tumours based upon the Sachs Georgi reaction but the details of his method are not very definite.

Remarks

BY

The value of accurate diagnosis of malignant disease, especially in early or latent cases, by a serological method does not require emphasis. Many attempts by various methods have been directed to this end, hitherto without conspicuous success, although the occurrence of profound changes, such as anaemia and cachexia, in the later stages of malignant disease would suggest the possibility of profound changes in the antecedent changes in the serum. Murray has recently brought forward some evidence of a toxic reaction evoked at one site in an animal which he suggests that there is some systemic constitutional change. If such be the case then it is not improbable that the medium of distribution of the locally produced toxin is the blood. On these grounds a serological method would appear a priori to be practicable. Experiments carried out by me in the laboratory of the Cancer Research Committee have shown that experiments carried out by me in the laboratory of the Cancer Research Committee have shown that

On these grounds a serological
reaction would appear *a priori* to be practicable
in experiments carried out by me it was found that
fixative properties often showed antigen in complement
in the urine. It seemed possible that a method
dispens with the colloidal flocculation reaction which
Moreover the fact that the Sachs (corg.) antigen employed
in Prof. H. field's laboratory was in gave a number
of positive reactions with serum from cases of carcinoma,
aid to indicate the possibility of obtaining a specific
precipitation reaction for malignant disease

The compound has been largely used to discover antibodies in the serum. This method was first used by Sato and Tera in 1923 and they were followed by many workers on this method. The reaction of the serum of cancer subjects and the reaction of the serum of normal subjects to the precipitin reaction of the serum of cancer subjects have been described by Weil and his associates. The reaction of the serum of cancer subjects and the reaction of the serum of normal subjects to the precipitin reaction of the serum of cancer subjects have been described by Weil and his associates. The reaction of the serum of cancer subjects and the reaction of the serum of normal subjects to the precipitin reaction of the serum of cancer subjects have been described by Weil and his associates.

(a) A 1 per cent alcoholic solution of cholesterol is prepared by dissolving 1 gram of cholesterol (Kahlbaum) in 100 cc of absolute alcohol in a glass stoppered bottle.

(b) Sterile normal (0.85 per cent) saline. The solution is made with distilled water and should be free from calcium and

3 Apparatus

(a) The trays flocculation used in the Sigma are those They are sterilized by dry heat

(b) The dropping apparatus for preparing the saline emulsion of antigen is shown in the drawing (Fig 1) It consists of a Win cluster flask tightly corked with a large rubber stopper through which pass (1) The tube the end of a Dr. The inner end is

in the Winchester (2) A tube to which a Higginson's syringe is attached for raising the air pressure inside the flask (3) A mercury U tube, which registers the air pressure inside the flask. The apparatus is very simple, and has been in constant use without attention for several years. Alternatively the Drejer Ward dropping apparatus may be used.

(c) Two water baths, one at 55° C for incubation of the serums, and an open one at 37° C (kept at constant level) for incubation. A simple constant level bath can be made by inverting a Winchester bottle full of water held in the rings of a retort stand so that the cork, which has a fairly wide hole through it, just meets the level of the water in the bath.

FIG. 2.

(d) An agglutinoscope for reading the results is useful. The one I have used consists of a wooden box, which contains a strip of light illuminating a slit in front of which is a tray with holes for the agglutination tubes.

4 Test Serums

The serums were obtained by venipuncture at the bend of the elbow with sterile precautions. The serum is allowed to stand in contact with the clot in the ice-chest overnight. It is then pipetted off, centrifuged free from red cells and heated at 55° C for half an hour. At first the serums were heated at 55° C for one hour but the shorter period has been found equally satisfactory. The serums after heating are not tested for twenty-four hours during which time they are kept in the ice-chest. Anomalous results were sometimes found if the serums were tested immediately after heating. This has also been found to be the case with the Sachs Georgi reaction (Browning and Macenzie²⁵).

Preparation of Saline Emulsion of Antigen

Immediately before use 0.1 c.c. of 1 per cent cholesterol (Krichbaum) is added to each 1 c.c. of diluted antigen. 1 c.c. of cholesterolized antigen is then placed in a graduated cylinder and saline is delivered drop by drop from the dropping apparatus from a height of 34 cm at a rate giving a dilution of 1 in 13 in one and a half minutes. The antigen is always freshly prepared, and is translucent faintly bluish and opalescent, and only slightly turbid. Only one dilution of antigen is used. Prepared in this manner the saline emulsions give the same degree of flocculation with a positive serum on successive days.

Arrangement of Test

Only four flocculation tubes are used for each test serum, the same serum dilutions are put up as for the Sigma reaction, omitting only the first tube containing 20 drops of pure serum. The 1 in 20 dilutions of serum were at first put up in addition, but it was found that even normal serums sometimes showed flocculations in the last tube of this dilution, and that some serums tended to flocculate in the last two tubes. As a routine, therefore, four serum dilutions have been put up, containing 10, 5, 2, and 1 drops of serum respectively, and 0, 5, 8, and 9 drops of normal saline. To the four tubes are added 15 drops of the saline emulsion of antigen. A control tube containing 10 drops of saline and 15 drops of antigen is put up, together with positive and negative controls. The pipette is washed with distilled water, alcohol, and ether, and dried, after use for each test serum. The tubes are shaken in order from right to left, and are incubated for three hours at 37° C in a constant-level water-bath. The water level is maintained at half the level of the fluid in the flocculation tubes. The trays are then stood overnight (about eighteen hours) at room temperature (about 18 to 22° C).

Readings

The tests are read after three hours, and again at the end of eighteen hours. With strong positive serums there is good flocculation at the end of three hours, which is much increased by the further period at room temperature. A weak flocculation, showing only traces at the end of three hours, is then easily visible. The flocculi are generally much coarser than in the Sigma reaction, and are visible with the naked eye without the use of a lens. They appear to be lighter, and do not sink to the bottom of the tube so readily as in the Sigma reaction.

"S++" indicates a degree of flocculation in which only a few large clumps remain in the fluid, or have sunk to the bottom of the tube. When there are coarse granular flocculi evenly distributed in the fluid and easily visible to the naked eye, this is taken as "S" reading. A "T₁" reading is only just visible to the naked eye. Turbidity less than this, visible only with a lens, may be neglected, as normal serums may give this degree of turbidity. Unless one of the four tubes shows an "S" reading the reaction is considered to be negative.

Source of Material

The serums were obtained chiefly from patients undergoing either in-patient or out-patient treatment at this hospital. In the case of malignant disease the clinical diagnosis is, in the majority of cases, been controlled by operation, microscopic sections, or post-mortem examinations. In the absence of such positive evidence, where there was doubt about the correctness of the clinical diagnosis the cases have been considered separately.

The control serums have been obtained from normal healthy individuals, male and female, and from patients with various diseases other than malignant undergoing treatment in this hospital. I am also indebted for control serums to the Central Laboratory, Ministry of Pensions, obtained from patients free from evidence of cancer.

In order to obtain a just appreciation of the value of such a reaction the elimination of bias in the readings is of the utmost importance. To prevent such bias the serums were numbered, the tests were put up, and the readings made without knowledge of the source from which the serums were derived. Only then were the results compared with

the information as to the clinical characters of the case from which the serum was obtained. Doubtful border-line readings have been classed as incorrect.

RESULTS

By this method 500 serums have been examined by three separate antigens. These antigens were prepared in a similar manner, but were derived from three separate sources. All were prepared from cases of carcinoma of the breast by the above method. The

first two were used undiluted and received only 0.05 c.c. of 1 per cent cholesterol per 1 c.c., the third was diluted 1 in 4 with absolute alcohol and received 0.1 c.c. of 1 per cent cholesterol per 1 c.c.

The results obtained are as follows. In 500 cancer and control cases a correct result was obtained in 75 per cent. Out of 239 cases of malignant disease the result was correct in 170 (71 per cent). In 261 controls of all kinds comprising healthy individuals and others with various diseases, 204 were correct (78 per cent). These results have been analysed according to the site or organ affected by the malignant process, to discover how the reaction is affected, and whether any light is thrown on it thereby.

Since the foregoing figures were compiled a further 125 serums have been examined by the third antigen, with correct results in 81 per cent of cases of malignant disease, and 82 per cent correct in the controls.

FIG. 3.—Tube 1 Saline control. Saline 10 drops + antigen 15 drops. Tube 2 Serum 10 drops + antigen 15 drops (dilution 1 in 25). Reading S+. Tube 3 Serum 5 drops + saline 5 drops + antigen 15 drops (dilution 1 in 52). Reading S+++ Tube 4 Serum 2 drops + saline 8 drops + antigen 15 drops (dilution 1 in 13). Reading S++ Tube 5 Serum 1 drop + saline 9 drops + antigen 15 drops (dilution 1 in 26). Reading S. Typical reaction with a cancer serum. Tubes 6, 7, 8 and 9 similar quantities. Completely negative reaction with a non-cancer serum.

TABLE I—Malignant Disease

Site of Disease	Number of Cases	Number Correct	Percentage Correct	Evidence Accepted of Malignancy		
				Clinical	Post mortem	Microscopical
A CARCINOMA						
Buccal cavity (excluding tongue)	29	20	70.0	18	—	6
Tongue	8	5	62.5	4	1	3
Oesophagus	5	4	80.0	2	3	3

	14	12	86.0	9	2	5
C LYMPHADENOMA						
	3	3	100.0	—	1	3
Total	239	170	71.0	102	21	120

Carcinoma

With all three antigens a high percentage of positive results is obtained with carcinoma of the alimentary tract. The high percentage shown by oesophageal (80 per cent) and stomach growths (75 per cent) is also noteworthy, as these are "inaccessible," and visible only by indirect methods. In cases of growths of the rectum positive results are much less numerous, and are amongst the lowest recorded (54 per cent). This is rather striking, and suggests that it may be due to the local character of the growth at this site. The stage in which most of the rectal cases were seen was early, with little or no spread. This was determined at operation by Miles's abdominal perineal method, and by subsequent examination of the parts removed. Where there were visceral deposits a positive result was often obtained.

Another striking feature is the low percentage of successes (58) given by breast cancers. This is all the more remarkable when one considers that all the antigens were derived from breast tissue. Here again it seems possible that the size and local character of the growth is the explanation, since a positive result was generally obtained if metastases were present.

These results contrast strongly with those obtained with carcinoma of the cervix and body of the uterus, in which the percentage of successes was strikingly high (87.5) and the flocculations were usually very well marked. The reason for this is evident, as most were advanced inoperable cases, though a few were operable. It may be mentioned that out of five negative reactions three were doubtful cases of carcinoma.

Bladder cases (86 per cent) and epithelioma of the skin (100 per cent), though not numerous, gave satisfactory results. In general, squamous-celled growths appear to react better than growths of glandular origin. Out of 222

cases of carcinoma of all sites and varieties 155 gave a correct result=70 per cent correct.

Size of Growth—With reference to what was said above concerning the size of the growth in the breast influencing the reaction, further evidence is afforded by rodent ulcers out of four cases, three, which were of very small size, gave negative result, while the fourth was very extensive and gave a strong positive reaction.

Sarcoma

The antigens reacted well with the serums of cases of sarcoma, the results showing that in 14 cases of all varieties, 12 gave a positive result=86 per cent correct. Sarcoma at all sites reacted equally strongly. This may be due to the fact that the blood stream is more intimately connected with, and therefore affected by, the sarcoma.

Three cases of lymphadenoma (Hodgkin's disease) were investigated, and all three gave strong positive flocculations. If the lymphadenoma are classed among the neoplasms of the lymphatic system, with Mallory and the American school this result may be regarded as correct, but if they are to be classed with the infective granulomata, the result would be incorrect. In any case, blood changes in the disease undoubtedly occur.

TABLE II—Controls

Type	Number of Cases	Number Correct	Percentage Correct	Evidence of Non-malignancy		
				Clinical	Post mortem	Microscopical
1 Non-malignant tumours	19	13	68.5	5	—	14
2 Healthy individuals	21	20	95.0	21	—	—
3 Syphilitic disease	15	11	73.0	15	—	—
4 Medical conditions	111	86	77.5	59	3	4
5 Surgical conditions (non-neoplastic)	95	74	78.0	62	1	28
Total	261	204	78.0	162	4	46

1 The non-malignant tumours, comprising papillomata, fibromata, adenomata, ovarian cysts, fibroadenomata, and an enchondroma, have been classed among the controls. The results obtained with them are rather difficult to assess. On the one hand, a few of the large tumours, such as fibroids of the uterus and adenomata, have given weak positive reactions. These have been classed as incorrect reactions. This accounts for the rather low figures of correct results (68.5 per cent). A large supporting ovarian cyst, discovered at operation, gave a strong positive reaction, as did a case of fibroids with an ovarian dermoid cyst. The papillomata, which were of small size, were uniformly negative.

2 Twenty-one healthy individuals gave completely negative results, usually without a trace of flocculation, except in the case of one female, whose serum gave a weak positive. A second sample of this serum at a later date gave a negative result. (As additional controls, serums from individuals suffering from various diseases other than neoplastic have been examined. These have been grouped for convenience into medical and surgical conditions.)

3 In view of the various flocculation reactions for syphilitic disease, the results obtained with the present reaction in the case of serums from syphilitics are of special interest, and have therefore been extracted from the general body of the results obtained in non-neoplastic diseases. It will be observed that in 15 cases of syphilitic disease of all stages except the primary, the reaction was negative in 11 (73 per cent of cases). These cases were all free from evidence of new growth. Where, however, new growth was present in conjunction with syphilis, as in certain cases of carcinoma of cervix or tongue showing a positive Wassermann reaction, a positive reaction was obtained. It is evident, therefore, that the reaction is different in character from the flocculation reactions for syphilitic diseases—a subject which receives consideration below.

4 The heading "Medical conditions" includes alimentary disorders, cardiac and blood diseases, diseases of the ductless glands, skin lesions, tuberculosis and other pulmonary conditions, and, in addition, indefinite or trivial disorders in patients attending the out-patient department, serums sent from outside sources, and the like. All were from patients considered free from malignant disease. In the alimentary disorders, gastric ulcer and dyspepsia, a high percentage (90) of correct results was obtained. Active pulmonary tuberculosis or other tuberculous conditions gave a rather large number of false positives. Over the whole series of 111 cases, comprising a great variety of medical disorders, 77.5 per cent of the cases gave correct negative results. Of the negative controls, 59 were definitely free from malignant disease on clinical grounds, 3 were verified by *post-mortem* and microscopic examination, and 1 by microscopic evidence only—a total of 63. Of these 63 definitely non-malignant cases negative results were obtained in 76 per cent.

5 Among the more frequent surgical diseases, gastric and duodenal ulcers, the majority of which were confirmed by operation, gave a good proportion of correct results (86 per cent). Breast cases also showed 86 per cent. One case of surgical tuberculosis (spinal cases) gave a strong false positive. Surgical conditions show the same total percentage of correct results as medical conditions (78 per cent). Of the above cases 80 were verified as non-malignant either by operation or direct examination, 28 of these being confirmed microscopically. In 5 cases the evidence was lacking. Among the 80 verified cases, 73 gave a correct negative result (81 per cent).

Evidence of Malignancy

Of the 239 cases regarded as malignant, evidence of malignancy was definite in 222, or 93 per cent. Of these, microscopic examination was carried out in 120, or 50 per cent of the cases, and *post-mortem* examination with microscopical diagnosis in 21. The clinical evidence was regarded as undoubted in 102. These were confirmed either by operation or by direct examination in the case of accessible growths. In these 222 definite cases of carcinoma, positive reactions were obtained in 158, or 71 per cent correct. This is about the same percentage as is obtained by the Wassermann reaction in untreated cases of syphilis of all kinds.*

Evidence of Non-malignancy

Of the 261 cases regarded as non-malignant 208 were verified, 162 upon clinical grounds, and 46 by microscopical and *post-mortem* evidence. Of these 208 cases, 164 gave a correct negative result (79 per cent).

Incorrect Reactions

A *False negative* was given by 69 of the 239 cases of malignant disease (28.8 per cent). Of the 222 verified cases 62 gave negative or doubtful reactions (28 per cent).

B *False Positives*.—Of 25 serums among the medical cases giving false positive reactions, no fewer than 14 (56 per cent) were derived from outside sources, and of the 21 false positives* given by serums from surgical cases 4 were from outside sources—13 in all. Concerning these 18 serums no satisfactory information could be obtained, though they were all believed to be from non-malignant cases. The conditions under which the serums had remained after withdrawal of the blood, and the lapse of time after withdrawal, were unknown. These conditions may have militated against a correct result.

Of the remaining 28 medical and surgical cases, 10 showed only weak or doubtful positive reactions. These have been placed in the scale against the reaction.

Value of Reaction in Diagnosis

In certain supposed malignant cases the flocculation reaction proved more accurate than the clinical diagnosis, for in no fewer than 34 cases its correctness was afterwards verified by operative, *post-mortem*, or microscopical examination. On the other hand, in 17 cases the reaction

supported the erroneous clinical diagnosis of malignant disease. In supposed non-malignant cases a positive reaction was obtained in 5 cases, which were subsequently proved to be malignant. On three occasions the reaction was incorrect.

Influence of Removal of Growth

Removal of a growth, provided that metastases are absent, appears to cause a diminution or actual inhibition of flocculation in some cases, though this has not occurred in all. Thus, in one case of carcinoma of the breast which gave a positive flocculation prior to operation, the blood, when investigated six weeks later, gave only a weak positive reaction. A second case gave only a doubtful positive flocculation previous to operation. On microscopic examination the tumour showed changes suggestive of early malignant disease. The blood, when examined ten weeks later, gave a rather stronger reaction. A third examination seventeen weeks after operation gave a definite positive reaction. The patient, after operation, had received *radium* treatment. On the other hand two patients who had had radical excisions of the breast and had no signs of recurrence, the one fifteen months and the other four years after operation, both gave completely negative reactions.

Two cases of carcinoma of the rectum, on whom complete excisions by Miles's abdomino-perineal method had been performed, without signs of recurrence four and a half and five and a half years afterwards respectively, gave negative reactions. In these cases flocculation reactions had not been performed prior to operation. A case of carcinoma of the body of the uterus, which had been extensively treated by radium, gave nevertheless a strong positive reaction, due, no doubt, to the abdominal metastases present.

Relation to Wassermann Reaction

In 487 out of the 500 cases Wassermann reactions were performed, two serums persistently proved to be anti-complementary. In all but 5 of the 239 cases of malignant disease Wassermann reactions were done, one serum being anti-complementary. Twenty-one positive Wassermann reactions were obtained among these 235 cases, including one case of lymphadenoma, in comparison with the 170 positive flocculations. On the 201 controls, 253 Wassermann reactions were done, one being anti-complementary. These gave 18 positive reactions. They were accompanied by only 7 positive flocculations. Among the latter was a case of fibroids and another of adenomyoma of the uterus. A third case, diagnosed as carcinoma of the uterus, proved to be chronic metritis.

It is evident from the above that the flocculation reaction here described is dependent upon factors different from those in the Wassermann reaction. The reacting substance in the serum is probably not euglobulin nor the globulin fraction upon which the Sachs-Georgi flocculation is said to depend (Browning and Mackenzie²⁵). The addition of an equal volume of a saturated solution of ammonium sulphate to the serum diminishes, but does not inhibit, the reaction. Further the antigenic substances are almost certainly different. This is shown by the fact that carcinoma serums rarely if ever react positively with the Syphilis antigen in the absence of a syphilitic factor even if used in the same dilution and treated in the same manner as the antigen here described.

FACTORS INFLUENCING THE REACTION

A Serum

1 *Heat*.—Positive serums do not flocculate unless they have been heated. No experiments have been done to show what is the least period of heating required for the reaction. Increase of time from a quarter of an hour to three hours does not appear appreciably to affect the result.

2 *Age of Serums*.—Serums appear to be unstable if the reaction is performed immediately after heating and variable reactions may be obtained. Hence the sera not examined for twenty-four hours after heating. Within

* Since the compilation of these figures one of the cases included therein has returned to hospital with a well marked cancer of the oesophagus verified by microscopical section.

limits, lapse of time after withdrawal of the blood does not seem to affect the reaction, positive serums giving approximately the same results on successive days. The reaction tends gradually to disappear. It is not known whether this occurs in sterile serums kept in sealed tubes.

3 *Infected Serums*—Absolute sterility of the serums does not appear to be necessary, but gross infection causes anomalous results.

B Antigen

1 *Dilution*—The antigen, unless diluted to a proper strength before the emulsion is made, may show spontaneous flocculation, or no flocculation may occur.

2 *Cholesterolin*—Flocculation does not take place, or is meagre, without the addition of cholesterolin. The flocculation is not so marked with the smaller amounts of cholesterolin.

3 *Saline*—The use of distilled water instead of saline for making the emulsion does not seem to prevent flocculation.

C Incubation

Incubation at 37° C for longer periods than three hours, up to twenty-four hours, does not increase the reaction. The reaction does not occur so readily at 55° C. If the trays are placed in the 37° C incubator after the three hours in the water-bath the reaction does not proceed so far as when they are kept at room temperature after the water-bath.

DISCUSSION

1 Nature of Reaction

In common with other colloid flocculation tests—for example, Sigma and Sachs-Georgi—the precise nature of the reaction is not at all clear, nor are the substances upon which the reaction depends any better defined. It is evident that the reaction is due to a diminution of surface tension in an unstable colloidal system, in the course of which aggregates are formed of visible size. The nature of these colloids is unknown.

2 Specificity

That this reaction is not at present absolutely specific for malignant disease is evident from the false positive shown above, notably with tuberculosis and certain febrile and other conditions, but the antigen has at least some specific relations with human serums.

(a) *Rat Antigen*—An antigen prepared in a manner precisely similar to the human antigen, from a rat carcinoma, gave no flocculation at all with carcinoma serums which had already given flocculations with the human antigen. An antigen prepared from this rat carcinoma according to the formula of Roffo,³ similarly gave no flocculation using the Sachs-Georgi method—a result opposed to those of Roffo. Moreover, cross-experiments with nine serums from rats grafted with rat carcinoma gave no flocculation with the human antigen, nor did they give any flocculation with the antigen prepared from their homologous tumour.

(b) *Lecithin-Cholesterolin Antigen*—An “artificial” antigen, prepared from a 1 per cent solution of ovalbumin (B.D.H.), diluted with alcohol 1 in 4, to which 0.1 ccm of a 1 per cent solution of cholesterolin per 1 ccm was added in a manner similar to the carcinoma antigen, did not react in the same way with carcinoma serums, although it showed in some cases flocculation with such serums. It seems clear, therefore, that the carcinoma antigen has some specific properties.

(c) *Cellular Disintegration*—The non-specific reactions which the carcinoma antigen exhibited seemed to be related to some extent to cellular disintegration. Thus, in the tuberculous cases there was considerable tissue or bone destruction. In the case of metritis, there was much cellular destruction and pus formation. Possibly the reaction may show some relation to the antitryptic index, though this has not been investigated.

(d) *Globulin-Albumin Ratio*—According to Locy and Tonniet,⁶ and others, cases of malignant disease show an alteration of the globulin albumin ratio in the serum. Wegner⁷ asserts that “the determination of the albumin globulin quotient must lead to the same result as the flocculation reaction—that is, a serum whose quotient is raised must flocculate easily.” Kennedy,⁸ has, however, shown recently that changes in the globulin albumin ratio occur only in the serum of advanced cases of cancer. Consequently this reaction would not appear to depend solely upon this factor.

(e) *Cholesterolin Content*—It seemed possible that the reaction might be due to the cholesterolin content of the serum reacting with a colloidal system highly saturated with cholesterolin, and that the variations in flocculation might be due to the amount of cholesterolin in the different serums. It does not seem to be certain whether there is any constant increase in the amount of cholesterolin in the serum in malignant disease. On the one hand, Liden⁹ and Gordon-Reeves¹⁰ have found an increase in the amount of cholesterolin in the serum of cancer patients, while Galea¹¹ finds that the amount of blood cholesterolin varies according to the site of the tumour, and some, indeed, have found hypercholesterinaemia. In this reaction serums which might be expected to contain large amounts of cholesterolin did not give a positive reaction in the absence of malignant disease. Cases of cholelithiasis, which contain a high percentage of cholesterolin in the serum, did not react positively. Increase of the amount of cholesterolin in the antigen did not change the character of the reaction, but merely increased the sensitiveness of the antigen. It seems that the reaction does not depend solely upon the cholesterolin content of the serum.

(f) *Lowering of Surface Tension*—According to Volz and Benedetti,¹² colloidal flocculation reactions are due to a lowering of the degree of dispersion of the globulin of the serum, and Hoyer¹³ considered that the interaction of the serum colloids with the colloids of an antigen is in the nature of an adsorption phenomenon between the surfaces of the colloids. J. Bauer¹⁴ states that there is a lowering of the surface tension of the blood serum and tissue fluids in carcinomatous diseases. If this is the case, then the formation of aggregates and flocculi through changes in the colloids of the antigen can be readily explained. If, however, it were simply a question of the lowering of the surface tension, one would expect cancer serums to form flocculi with any antigen—for example, the Boidet and Ruelens antigen of the Sigma test. As has been shown, however, this is rarely the case, so that the antigen used in this reaction would appear to have some additional specific properties.

SUMMARY

1 Over the whole series of 500 cases, comprising malignant and non-malignant conditions, 75 per cent correct results were obtained.

2 In 239 cases of malignant disease, 170 positive flocculations were obtained (71 per cent correct).

3 In 261 controls, comprising healthy individuals, cases of non-malignant neoplasms, medical and surgical conditions, 204 gave a negative result (78 per cent correct).

4 Healthy individuals gave a uniformly negative reaction, except in one instance.

5 Non-malignant tumours usually give a negative reaction.

6 In the absence of malignant disease flocculations do not in the majority of cases occur with syphilitic conditions, but a control Wassermann reaction or Sigma reaction is advisable.

7 With acute febrile conditions—for example, tuberculosis or sepsis—positive flocculations may occur.

CONCLUSIONS

1 The preparation of an antigen and arrangement of a simple flocculation reaction has been described. This reaction gives a high percentage of correct results, both in malignant and non-malignant conditions.

2 Including certain conditions, the reaction is of value in the diagnosis of malignant disease

NASAL, AURAL, AND OTHER FOCAL SEPSIS AS A CAUSE OF NEURASTHENIA AND INSANITY

BY

PATRICK WATSON-WILLIAMS, M.D. F.R.C.S.,

CO-SULTING SURGEON FOR MISEASES OF THE EAR, NOSE AND THROAT,
BRISTOL ROYAL INFIRMARY

The purport of this communication is first, to draw more widespread attention to sepsis as often the essential cause of functional psychoses, arising from slight blunting of intellectual activity, through the more definite forms of rhinoinfection, inability to concentrate, unsociability, and the various syndrome of psychic abnormality grouped under the terms "neurasthenia" and "hypochondriasis," to the graver manifestations of unsoundness of mind accompanied by suicidal impulse, delusional insanity, mania and ultimately dementia praecox, and secondly, to lay stress on the import of the fact that the sepsis is most frequently what is conveniently termed "focal" and "latent" or "cryptogenic."

Many years ago I held a post of resident clinician in Stratford Winson Green Asylum, where there were about 600 inmates, and to which the acute cases occurring in and around Birmingham were mostly sent. One could not fail to be impressed with some of the acute manic cases which were apparently cut short by a blue pill and active treatment of the gastro-intestinal tract. It is now generally accepted that general paralysis of the insane is a legacy of syphilis, and alcohol and toxæmia of gastro-intestinal origin are recognized as causes of functional psychosis of toxic origin. The number of cases of insanity due to apical dental sepsis and cured by extraction of often long teeth is growing rapidly. It is because it is not as yet widely known that focal sepsis of the nasal sinus tonsil, and even my cause functional psychosis and insanity that I desire to emphasize the importance of not overlooking such sources of mental trouble, without, however, contending that therein lie the most frequent source of sepsis causing mental aberration. Nor do I touch here on a subject I have elsewhere discussed—the question of focal sepsis as a cause of mental delinquency and crime—although a fruitful subject if approached with judgement as a matter requiring careful deliberation. On defective delinquency and functional psychosis the splendid work carried on at the State of New Jersey's mental hospital, as described by Dr. Henry Cotton,¹ is worthy of most careful attention.

In 1907 in the Long Fox Lecture¹ I stated that—

All patient suffering from purulent sinusitis are liable to suffer from general toxic symptoms toxic products reaching the blood either from direct absorption from the implicated sinuses or from

the gastro-intestinal tract but lymphatic absorption of toxic matters, in the presence of channels of communication with the intracranial venous sinuses must be held to account for the profound mental depression and difficulty in thinking clearly almost amounting to slow cerebration that is very frequently present in frontal ethmoidal or sphenoid ethmoidal sinus suppuration and some times a less marked degree, even in simple maxillary sinus disease. Many patients have come with drawn and expression and sallow complexion expressing their weariness of life and a profound melancholia which was quite foreign to their natural state of mind—symptoms which have completely disappeared with the removal of their sinus disease, sometimes it has been difficult to recognize in the round faced cheerful individual one who shortly before bruted it as a haggard melancholic.

Up to sixteen years ago I had never met with a case where definite mental aberration preceded and was relieved by necessary sinus treatment, though many of my patients were the subjects of a psychosis and several had confessed to strong suicidal impulses. Shortly after this I encountered examples of definite insanity. The most remarkable in my experience occurred in 1911. It will be more useful to relate this one case at some length than cite many cases, some of which I have already published.²

A healthy looking well nourished man aged 29, keen and good at outdoor games shooting and so forth had a severe attack of influenza in 1901. In 1903 he had his first definite appendicitis. Appendicectomy was performed in 1907. This was followed by insomnia, for which he went on a voyage to Madeira.

Recovery seemed complete and till early 1911 he was very bright full of fun and keen on politics and his work. (Acquired relative immunization). In February 1911, he had influenza with bad headaches and general malaise but not badly, so did not stay in bed and went on till insomnia compelled him to give up work and go away for five weeks. He returned then miserable and depressed. He tried to work for the next two months, his doctor advising this as it would take his mind off himself but he found it impossible to continue. He was sent on a voyage but seemed in a mental mist all the time and terribly depressed. (After he told me, he took a pistol with him intending to shoot himself.)

When I saw him in August 1911 he looked ruddy and well nourished but had been obliged to give up work though he still played fairly good golf. But he said his memory was gone he could not think and his mind was a blank. He had post nasal discharge which he had been told was of no importance. I found fetid pus in the one nostrum explored. He travelled to Bristol wandering up and down the train corridor the greater part of the night and could not sit still. He declared he was "devil driven" and that it was a sin to have an operation, because he was dead. Mr. Stook gave an anæsthetic on September 25th, 1911 and I opened both maxillary antra which contained fetid pus and from the frontal sinuses pus was washed out. Lavage of frontal sinuses and antra was continued daily but his delusions became morbid. He refused all food because he was dead. The matron of the home said she feared to keep him because he was insane and ought to be under certificates but instead of certifying with his parents consent I operated again on October 29th, assisted by Mr. A. J. Wright performing my radical osteoplastic flap frontal sinus operation. The frontal sinuses were unusually large and the mucosa much diseased. Cultures from the antra and frontal sinuses yielded pure *Staphylococcus aureus* (J. Walker Hall).

For several weeks he refused all food and had to be forcibly fed by male attendants. He tore off his dressing when he got the chance.

He went home on December 3rd with the operation wounds healed mentally much improved but still subject to delusions of having committed unpardonable sins even then at times he refused food and declared he was dead. His delusions continued for some months but they became progressively less dominant and less than a year later he was writing sensible letters full of interest in life. Very soon after that he was back at his work since then he has remained in excellent health and has occupied a responsible position for a period of twelve years.

I would emphasize the following points in this case

(a) The long history of sepsis following influenza in 1901 with gastro-intestinal infection and appendicitis probably of nasal origin—a by no means infrequent occurrence.

(b) After a period during which the infection was inhibited by auto-immunization a second attack of influenza caused a relapse and the nasal sinus infection caused profound mental disturbance—melancholia with resisted suicidal impulses. Despite a prolonged holiday and a voyage he could no longer regain the power of work, and he then developed delusions.

(c) He did not lose his delusions for several months after disinfection and detoxication, but after his general health had been restored he regained all his old mental activity and general health and has continued to occupy a position of responsibility without intermission.

(d) The patient was undoubtedly insane, and apart from the symptoms related, the letters in my possession that he

¹ This paper and the three papers that follow it were read before the Bath and Bristol Branch of the British Medical Association at the University of Bristol May 27th 1925.

wrote prior to operation on his frontal sinuses suffice to demonstrate his delusional insanity. And he been satisfied as means it would have been a matter of great difficulty for him to regain the confidence of his bank directors.

(c) Bacteriological examination of the nasal sinus contents demonstrated pure culture of *Staphylococcus aureus*, so often regarded as of little import. Teeth and tonsils were not involved, his previous appendectomy had apparently removed the only other involved focus of infection, making his a pure nasal infection case.

Let me refer very briefly to one example at the other extreme—the very mild type of chronic nasal sepsis.

A man, aged 56 complained of deafness with post nasal catarrh, never severe, but of twenty-seven years' duration. He had been tired off and on during that long period, but latterly had been getting depressed, lessened mental acuity causing difficulty in carrying on his work, he complained also of general muscular weakness. Exploration of his nasal sinuses revealed no obvious pus, but Dr Todd, who examined the extracted contents found, together with polymorphonuclears, streptococci and Friedländer's pneumobacillus in the right sphenoidal and posterior ethmoidal cells, the other sinuses being sterile. The infected sinuses were opened and drained and he soon felt stronger, increased in weight, and, as he put it, brighter than he had ever done for years past.

It is certainly not intended to suggest that all patients whose tonsils, sinuses, ears, or teeth are mildly infected must be operated on, or that they are the subject of functional psychoses, any more than is the individual who is somewhat melancholic because his liver is sluggish or he is constipated. Few individuals are there who, in the course of common colds or influenzal attacks and so forth, have not been the subject of transient nasal sinusitis, fortunately the great majority of such infections clear up spontaneously by auto-immunization, or with the appropriate measures of ordinary medication, while every medical practitioner knows that rest, feeding up, change of air, and so on are very often all that is required to obtain complete cure.

It is cases of chronic sepsis with mental depression and neurasthenic symptoms which do not yield to ordinary medicinal measures, or that seem to clear up only to recur, that we need to recognize, and to associate the functional psychosis with the physical abnormalities that may be the underlying and removable cause.

It is necessary to emphasize the "latent" or hidden character of the focal sepsis in many patients who nevertheless are the worst sufferers from chronic toxicæmia. First, there is often an absence of pain or other symptoms directing attention to the real source of infection, and, secondly, it is significant that patients with chronic copious purulent discharge but seldom suffer from toxicæmic symptoms as compared with those with little discharge, and that often non-purulent to the naked eye. Many years ago I suggested

that in the numerous polymyositis in the one case, as contrasted with the purity of polymyositis in the others, we have an explanation of the remarkable differentiation to which I have drawn attention.¹ Subsequent experiences have borne out the truth of this, and in the latent character of apical dental sepsis, which often enough can only be detected by radiograms, we have a further exemplification of the cryptogenic character of some of the most potent sources of focal sepsis.

If it be recognized that owing to the existence of focal sepsis a considerable percentage of patients are miserable, the subject of neurasthenia or of functional psychosis of grave character, rendering their lives more or less useless to themselves or a source of danger to the community, it is hardly necessary to urge the duty of ferreting out these septic foci—which involves regard to the gastro-intestinal tract (for example, for evidence of colitis, enteric ulceration, appendicular infection), to the genito-urinary tract, the teeth, fauces, nasal sinuses, the ear, and so forth.

In such investigations we must often invoke the aid of radiology, of analysis of gastric contents and of the feces. How many asylums to day have such essential resources at their disposal? Yet within a few years I believe that with each one will be actively associated a consulting physician, surgeon, dentist, radiologist, laryngologist, and pathologist. Let us cast no stones, for hitherto we as a profession have barely recognized the symptoms which should call for the elimination of focal sepsis as the *fons et origo* of some patients' afflictions in whom the ostensible diseases are

merely the end results. Of this we may feel assured—sepsis is a far deadlier foe to civilized races than tuberculosis.

ON AURAL FOCAL SEPSIS AS A SOURCE OF NEURASTHENIA AND INSANITY

BY

P. WATSON-WILLIAMS, M.C., CH.M.,

CLINICAL LECTURER IN LARYNGOLOGY AND OTOTOLOGY IN THE
UNIVERSITY OF EDINBURGH

It has long been recognized that disease of the ear may lead to mental disturbance more or less severe. Even so simple a matter as removing a plug of wax has been recorded to have cut short an attack of mania. As regards aural suppuration, attention in the past appears to have been directed in this connection to deafness, tinnitus, pain, vertigo, and intracranial complications. In short, only disease of the organ of hearing, and local complications, seem to have been considered. With such I am not here immediately concerned.

Many instances of the association of one or more of these conditions with mental trouble have been recorded. Tinnitus especially is noteworthy, some writers even go so far as to say that most cases with hallucinations of hearing ought to be classed as suffering from delusions, there being some definite aural lesion to account for their symptoms. Vertigo is well known to induce definite neurasthenia in some cases. We ought to be careful that disinclination to mix in traffic, or a shivering from work, say, as a stoker, or on a scaffolding, is not incorrectly ascribed to neurasthenia, when really due to laudable prudence. I have had the good fortune to see both this false neurasthenia and a true neurasthenia disappear when suitable treatment has relieved the vertigo. A few cases of intracranial abscess have been published where treatment has relieved a definite psychosis, but too many of the records showing this association are from autopsies, no treatment having been instituted. I may summarize the situation by recalling the plea of Forrester¹ which, in 1901, he added to a record of a case successfully treated—that every patient suffering from mental change should have the ears examined. In the same year Dr. Bernard Hollander wrote

By these cases one is forcibly taught the lesson that an apparently slight and unimportant ailment such as a running from the ear, which is apt to be looked upon as an inconvenience rather than a disease, may prove very dangerous.

TOXÆMIA

Putting aside these local manifestations, I shall omit all cases in which tinnitus, vertigo, or intracranial complications were known to be present, and all cases in which there was not a family history free from mental taint, and shall confine myself to those instances in which surgical treatment of aural sepsis brought relief from the mental symptoms.

Towards the close of last century much attention seems to have been directed to the question whether toxicæmia was a factor of importance in the causation of insanity. Among the records of many discussions, perhaps the most interesting is that at the Medical Society of London on May 11th, 1896, opened by Dr. A. M. Hamilton of New York, on "The connexion of autotoxa with certain forms of insanity." The idea that chronic septic absorption could

produce "toxæmia" was not, however, then current, the word was applied rather to poisoning from the presence in the circulation of products of abnormal metabolism, or the result of intestinal stasis. It is not surprising, therefore, that at that time little attention appears to have been given to the middle ear tract as a possible source of chronic toxæmia. But it is now over fifteen years since West and Scott³ pointed out this possible complication. It seems noteworthy that even now the possibility is in some danger of neglect.

NEURASTHENIA

Perhaps for this reason the evidence I shall put forward is less complete than its importance deserves. It is not common in aural practice to find cases of definite insanity. Far more usual is it to see patients with minor disturbances, such as are usually described as neurasthenia. It is remarkable how regularly the same group of mental symptoms occurs in all descriptions of toxæmia, whether considered from a general or a local aspect. There is a sort of mental lassitude, the victim finds that the effort demanded by social duties is becoming too great, work which formerly he performed with ease and pleasure has become laborious, when he forces himself to work, he cannot concentrate his mind, he feels he has lost his initiative, memory may fail or more typically become "patchy", and to make a decision even on some quite minor matter involves a disproportionate effort.

A sufferer from such a condition came to me two years ago. He told me nothing of his trouble, but sought advice for a running ear. I carried out a radical mastoid operation for purely local conditions. Some months later he came to tell me of his neurasthenia, which all his friends had noted. After the operation the whole of the train of symptoms which were practically identical with the series I have indicated above, completely disappeared.

Another case was that of a chef. He had had to give up his work and though he had been trained in a less strenuous occupation he found this also was too great a strain. There was some physical evidence of toxæmia but the most marked feature was his depression and hopelessness. A short fortnight after the operation on his ear—which was performed mainly on account of the general condition—the change in his whole bearing was remarkable. He became bright and cheerful, got work at a big hotel as head chef and has been hard at it ever since—a matter of three years.

EPILEPSY

For statistical information on the association of ear disease with epilepsy I would refer to a paper by Dr Omerod.⁴ He found an incidence of epileptic fits several times greater in the subjects of otorrhoea than in the hospital population generally. I will cite a case in my own practice.

A man of middle age came to me for otorrhoea of old standing rather profuse and associated with some pain but not much. He was also subject to fits described by his doctor as epileptiform. While other treatment was being tried for the ear, the fits became more frequent—one or two every week. I therefore operated on an extensively diseased mastoid. This was only ten weeks ago but he has had no fits since the operation, and the outlook is distinctly promising.

INSANITY

Undoubtedly the most dramatic and convincing cases are those in which definite mental derangement has yielded to surgical treatment. The earliest case that I have found to illustrate my thesis is reported by L. Merz.⁵ In this definite association of mental disease with otorrhoea was noted before operation on a chronic mastoid abscess resulted in restoration to mental health. Nearly fifty years ago Dr W. Rhys Williams recorded a very striking case.⁶

A man aged 26 married family history, negative general health good, always industrious and sober. Thirteen days before admission to Bethlem he became depressed and rambling in his speech. Then he became excited, violent and incoherent. He had delusions: (1) that he was firing rockets at Edinburgh Castle; (2) of seeing devils; (3) of persecution by electricity. No aural symptoms were noted but he was noisy and sleepless. After admission he was sullen and quiet but a fortnight later he was again raving. Ten months after a discharge was noticed from the left ear. He stated that he had had this for a long time. Mastoid tenderness and swelling were observed, and a chronic abscess of the Bezold type was treated three operations being performed and 'he became sane at once'. Shortly after he was discharged cured.

I showed at the meeting of this Branch in January last a man who had had mild otorrhoea very chronic with no serious local symptoms. He had been comfortable under palliative treatment

for some months. But somnambulism with a habit of lighting fires and even more serious derangements of conduct developed and it appeared that he was going to become certifiably insane. I performed a radical mastoid operation with the happy result of completely relieving his mental condition and he remains well and is at work.

SUMMARY

What deductions are we to draw from these cases? It will not be disputed that an examination of the ears should be a part of the routine examination of every subject of mental disease. But even where there appears no local condition calling for surgical treatment, if we suspect that focal sepsis is at the bottom of the trouble, we must not forget the ears when seeking a possible source of that trouble. This is not less important when dealing with cases of milder mental disturbance, for the patient may think the running ear of little moment and omit to mention it, but such cases seem to yield comparatively readily to treatment. Finally, when considering the question of operative treatment of otorrhoea, we must have in mind the possible effects on the general health, mental as well as physical, of septic absorption from this source.

FOCAL SEPSIS AS A FACTOR IN THE CAUSATION OF NEURASTHENIA AND INSANITY

BY

J. A. NIXON, C.M.G., M.D., F.R.C.P.,
PROFESSOR OF MEDICINE, UNIVERSITY OF EXETER

This question of mental disturbances from focal sepsis is most important, but sufficient attention has not been given to it in the past. It serves to emphasize the absolute necessity for a most scrupulous examination of every patient suffering from neurasthenia or graver mental trouble. This is, indeed, only fair, for there might be found some definite lesion to account for what had been thought an hallucination. In one case, it was alleged as a sign of insanity that the patient said he had a cannon-ball in his chest, this man was found, on x-ray examination, to have a large and unsuspected aneurysm.¹ Further, it is remarkable what gross damage may exist with apparently little mental change; it is necessary to be on guard that a serious intracranial lesion is not overlooked.

In considering the mental changes associated with focal sepsis, I might instance for comparison the well known mental disturbances associated with the onset of infective fevers such as typhoid or pneumonia. If an acute infection could so much disturb the mentality in a few hours, it should cause no surprise that a chronic toxæmia could produce insanity in the course of months. I propose, however, to leave out of account the acute fevers, as not being within the scope of "focal sepsis."

The cases in which chronic septic absorption appears to be a definite factor in causing mental disturbance are of the greatest interest and importance. I will relate one or two that have come within my own observation.

Case 1—Just before the war I was called to see a young professional man who had attempted to commit suicide. The family history was exceedingly bad and it was at first thought that the prospect of mental recovery was poor. An alienist called in consultation took a different view. He observed that the periods of depression to which the patient was subject coincided with attacks of constipation so severe as to be absolute for eight or ten days together and he was strongly opposed to the man becoming an inmate of an asylum even as a voluntary boarder. Advice was given as to the proper regulation of the bowels, and the patient was put in the care of friends. He completely recovered and has been since 1916 an active and hard working man.

Case 2—A woman was admitted to hospital with acute mania. Observation showed that she had always a slight daily rise of temperature. Further investigation revealed infection by *B. coli* of the urinary tract. Under treatment this was relieved and simultaneously the mental state became normal.

Case 3—A working quarrryman, a man of poor education became during the war the owner of a quarry and the possessor of considerable wealth. He began to suffer from delusions and

melancholia and was soon quite insane. It seemed clear that his altered circumstances and the responsibilities of ownership and management had brought about his downfall. He had however a very septic mouth, extraction of all his teeth was followed by complete restoration to mental health.

Case 4—In this instance a man had no fewer than three sources of septic absorption: he suffered from chronic nasal sinus disease, from dental sepsis, and from chronic appendicitis. The mental state was one of extreme introspection, with definite suicidal tendencies. Surgical treatment of all three foci has been carried out. It is six weeks only since this was completed. He says he is 'a new man'. Although the history is so recent, it is full of promise.

I think it probable that most of the cases of puerperal mania are septic in origin—perhaps the actual focus of infection is small and the grade of infection low. The important point seems to be that, if in a given case of mental disease we can find the cause, and eliminate it, we shall be able to give a good prognosis. This good prognosis we are accustomed to give for example in cases of post-typhoid insanity, because we recognize that the toxic state does not last. It is therefore of the greatest importance that we do not overlook any source of chronic poisoning when called upon to examine a patient with mental disturbance. A careful and thorough physical examination is more likely to be fruitful than investigation of the origin of the mental state along psycho-analytical lines.

FOCAL SEPSIS OF DENTAL ORIGIN CAUSING MENTAL IMPAIRMENT

BY

W. R. ACKLAND, M.D.S., M.R.C.S.,
CONSULTANT DENTAL SURGEON, BRISTOL LOCAL INFIRMARY

It has not been my fortune to treat any cases of definite insanity, but I have had a number of cases showing severe if non-certifiable mental impairment. I think my best contribution to the discussion will be to give you a short account of three of these.

Case 1—The brother of a professional man was brought to me during the war. He was a soldier on sick leave and for eight months there had been no improvement in his condition. He showed the most extreme degree of apathy. If sitting at table he would get up for something and forget before he had taken two steps for what he had risen. In speaking he would leave out words or break off in the middle of a sentence unable to finish. He was dull and listless, dispirited, slow, tremulous and uncertain in his movements. His complexion was a sickly earthy colour. He had some dull dental pain, which did not seem to be a matter of importance, but he had been persuaded to seek advice for this symptom. His mouth was in a terrible state full of crowns and bridges the roots supporting which were mostly suppurating. Under general anaesthesia a complete clearance of the offending teeth was made. Within a fortnight the good effect was apparent. His colour improved, his health became normal, his spirits returned and his mind became alert. He returned to his duty and has remained well since.

Case 2—A clergyman on a visit to Clifton was brought to me on account of offensive breath. His appearance was dreadful, his colour ashen grey, his speech slow, hesitating and indistinct. He showed an absolute lack of initiative and volition, and simply did what he was told in everything. He had had to give up his work owing to loss of memory. I found a mouth full of pyorrhoea with teeth mostly loose, and the odour beyond description. A complete dental clearance was made. His health, physical and mental, was restored to normal, he was able to go back to work, and has been busily employed ever since.

Case 3—A woman, aged 38, was white haired, wasted, and looked 50. So great was her mental torpor that she showed a long latent period between hearing a question and giving the answer, so that one was inclined to think her deaf. The answer when it came showed that her mental processes were sound. She was suffering from sleeplessness and neurasthenia, and was extremely thin. Her mouth was in a shocking state, the few teeth she had left were either loose from pyorrhoea or dead and affected by periodontitis. All the others had fallen out. Extractions produced a marvellous effect.

It is interesting to consider the route by which the toxin in these cases reaches the general circulation. In what for convenience I call the "open sepsis" of pyorrhoea the poison is swallowed, and perhaps, for a time, does little general harm. But presently the gastric defences break down, and absorption occurs. On the other hand, in the "closed sepsis" of apical abscess the absorption is directly into the circulation. In either case the toxin in the circulation probably directly affects the brain.

DISEASE OF THE ANTERIOR ETHMOID CELLS AS A CAUSE OF OPTIC AND RETROBULBAR NEURITIS

BY

J. A. GIBB, M.D., M.Ch.,
SURGEON TO THE EAR, NOSE & THROAT DEPARTMENT OF THE
WEST COAST ORTHOPAEDIC HOSPITAL, GLASGOW

So far as I am aware there are no recorded cases of optic neuritis and retrobulbar neuritis due to disease of the anterior ethmoid cells.

During the last eighteen months four cases of optic neuritis and one of retrobulbar neuritis have been referred to me for examination by Mr. Potts, the surgeon to the ophthalmic department of this hospital, in each the evidence that the anterior ethmoid cells were diseased was definite. With the exception of the case of retrobulbar neuritis there was evidence that the maxillary antrum was involved, no doubt secondarily. Logan Turner and J. S. Fraser have drawn attention to the fact that a definite condition of the eye and a definite condition of the nasal sinuses or antrum should be present before operation, and that it should be clearly directed to the particular nasal condition. The surgeon should have a clear knowledge of the position and relationship of the various nasal sinuses. An x-ray photograph will show if any of the cells are abnormally placed. Transillumination of the frontal sinus and maxillary antrum is an important aid in diagnosis. The directional action of the everted epithelium lining the various cavities should be known.

It is now known that nasal sinus disease may be a cause of albuminuria, arthritis, and certain toxicæmias. These are distant infections, and are amenable to operation on the affected sinus or sinuses, but the question arises whether the bones walls may become affected and infection thus spread to the overlying optic nerve. This may be possible in disease of the sphenoidal sinus and posterior ethmoid cells, but does not seem possible in the case of disease of the anterior cells. If infection does not spread by the blood stream nor by contact then I would suggest that spread takes place by the lymphatics. The lining membrane of the orbit and the sheath of the optic and third nerves are continuous, and the lymphatics must be continuous. Moreover, the nasal lymphatics can be injected through the lymphatics of the frontal region.

DIAGNOSIS

Cross infection of the sinuses with a large flow of pus, with swelling and moisture of the mucous membrane of the nares, does not seem to be a necessary condition attending optic nerve disease. The most severe cases are those in which the mucous membrane is dry and the pus thick and scanty. In them operation yields the most favourable and dramatic results. In anterior ethmoid disease pus is seen in the anterior part of the middle space, and in the posterior nasal space it is seen winding round the Luschka's cartilage. The position of the referred pain is a useful guide to anterior cell disease. It is assumed that cases of optic neuritis due to causes other than nasal sinus disease, such as cerebral pressure, cysts, etc., of the pituitary fossa, testicular syphilis, or nephritis, will not come into the hands of the rhinologist, but he should be able to say quite definitely whether or no his help will be of use. If the relationship of the rhinologist and the ophthalmologist had been closer in the past, as present-day knowledge impels it to be, then Mr. Rudyard Kipling would have wrought a happier ending in his book *The Light that Failed*.

OPERATION

I remove as little as possible of the middle turbinate bone. Anterior turbinatectomy is all that is necessary. In a punch forceps and a small ring knife to open the cells. Complete excitation may be necessary, and I have even felt the instrument to be in contact with the soft tissues of the orbit. Ecchymosis of the eyelids sometimes follows, it causes no inconvenience to the patient and is soon absorbed. I use lavage for some days previous to operation, if improvement takes place then no operation may

be necessary. An important matter in the after-care of these cases is warmth and free ventilation. If I quote the notes of two cases I think it may be sufficient.

CASE I

I was sent for on July 1st to see Mrs. J., aged 82. She complained of pain in the left eyeball and along the superior maxilla and almost complete blindness of the left eye. There was ptosis of the lid and the eyeball could only be moved slightly outward and downwards; the pupil was contracted. I referred her to Mr. Lott, who reported well marked optic neuritis, central scotoma, paralysis of the third nerve and slight proptosis; he suggested that I might find some nasal trouble. She gave a history of an influenza cold in her head some few weeks previously. Examination showed swelling of the middle turbinate with mucopurulent discharge in the middle anterior part of the space, and in the post nasal space over the Eustachian cartilage, the maxillary antrum was dull. I advised operation as a possible cure. She consented and three days later, under general anaesthesia, I completely excised the anterior cells up to the soft tissues of the orbit. There was ecchymosis of both eyelids. Six weeks later she had completely recovered her sight and movement of the eyeball and ptosis and proptosis had disappeared.

CASE II

F. C., a gardener, aged 22, was admitted to the eye department of the hospital on October 11th, 1924. Receding optic neuritis of the left eye was diagnosed. He complained of severe supra-orbital headache and occasional occipital pain, that he felt giddy, was sleepy at times and of nausea. On examination I found slight mucopurulent discharge coming from under the anterior end of the middle turbinate bone. In the post nasal space pus was seen winding round the left Eustachian cartilage, there was a similar condition on the right side but less marked. The report as to vision was R.V. = 6/5 (part) L.V. = 6/36. There was slight hyperaemia of the left disc, physiological pit filled in, and lamina not visible.

On October 12th left vision = 6/60. The following day, under general anaesthesia, the anterior ethmoidal cells were opened, right and left gently curetted, both maxillary antra burred and pus evacuated from the left.

On October 16th left vision = 6/36 and on October 27th 6/18. On April 23rd of this year it was 6/12. There is no active optic neuritis now present and vision is practically normal. This case was shown at the laryngological meeting in May, 1925.

ARTHRITIS DEFORMANS: OBSERVATIONS ON ITS ETIOLOGY AND TREATMENT

(Preliminary Communication)

BY

L. S. ASHCROFT, L. CUNNINGHAM, T. P. McMURRAY,
AND H. S. PEMBERTON

(David Lewis Northern Hospital, Liverpool)

Under the term "arthritis deformans" (Vuchow) we have included all forms of non-specific hypertrophic or idiopathic, active or inactive, arthritis which we have encountered in a routine investigation of upwards of fifty cases, seen in our wards and privately. This investigation has been conducted from several sides.

1. *Clinical*.—Daily observation has been made in the wards for as long, in some cases, as six months.

2. *Bacteriological*.—The joints have been opened (T. P. McM.) in a large proportion of cases, and from them an organism has been recovered (L. S. A.) which is identical in every case in its cultural and biochemical features. This organism does not correspond to any organism which has been previously described in association with this or any other disease, in so far as we have examined the literature. In only one case has it been recovered from the synovial fluid, in all the others it has been isolated from either the membrane or articular bone. No lesions have as yet been produced in animals, so far only the intravenous inoculation of rabbits has been attempted. Nothing constant has been isolated from foci of sepsis, faeces, urine, blood, or fasting stomach contents.

3. *Metabolic*.—Routine examinations have been made (L. C., H. S. P.) of gastric secretion, basal metabolism, acid-base ratio, renal and hepatic efficiency, and of glucose tolerance. The outstanding features, so far, appear to be the large proportion of cases showing achlorhydria or hypochlorhydria, the practically universal diminution of carbohydrate tolerance, and the relative absence of acidosis, renal or liver defects, or of changes in the basal metabolic rate.

4. *Therapeutic*.—Apart from correction of deformities (T. P. McM.) and removal of focal sepsis wherever practicable, the only routine treatment employed has consisted in the use of large amounts of 0.4 per cent hydrochloric acid and a carbohydrate-free diet extending over a period of months. Improvement—first by diminution of pain and then by increase of mobility—has been obtained in practically every case, even without the removal of focal sepsis.

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF REVERSE PERISTALSIS

A congenitally weak-minded boy, aged 13, recently had an attack of diphtheria, which was treated with antitoxin in ordinary doses. About ten days after his admission to hospital, and after all acute symptoms had passed off, he became very constipated and lost his appetite, his tongue becoming furred and dry. Ordinary aperients failing to produce an action of the bowels, a simple enema was administered. This was retained for about three quarters of an hour, when it was returned unchanged, he vomited at the same time, and the motion noticed in the vomit several pieces of oval brown substance, rather less than the size of a small walnut. On examining these about an hour later I found them to be typical, formed faeces. The boy was then quite comfortable, he had had the bowels moved, though by the mouth, and his tongue had already cleared. He has since made a perfect recovery, and his bowels have become normal after the use of aperients.

The enema appears to have set up a reverse peristalsis which carried the faeces from the colon to the stomach in something less than three-quarters of an hour.

ROBERT E. LORD, M.D., B.Sc. Lond.

PROLONGED CHEYNE-STOKES RESPIRATION FOLLOWED BY RECOVERY

THE following case seems of sufficient interest to be placed on record.

A male infant 1 month old, was brought to the CMS Hospital Pakhoi, South China, at 11 a.m. on May 9th, 1924. The child was cyanosed, the temperature was 99° F., the pulse was very feeble (160), and the respirations very irregular (50 to 60). As there was some history of cough it was for the moment thought to be a case of bronchopneumonia but auscultation of the chest showed nothing abnormal, and suspicion fell on the alimentary system. The mother, who lived on a junk, said that as she had been short of milk she had, the previous day, given the child a quantity of 'yeet'. This concoction very popular among the local Chinese is made of flour, cane sugar and boiling water. Castor oil was given at once and 3 minims doses of brandy, diluted at intervals.

At 2 p.m. the temperature had fallen to 98° F. and the respirations had become markedly irregular and finally, an hour later, assumed the Cheyne-Stokes type. The temperature rose to 100° F. At night the condition of the child was critical. The breathing cycle was of 7 to 9 respirations, the pulse was very feeble and difficult to count. An injection of digitalin gr. 1/1200 and strychnine gr. 1/1200 was given, and a rectal saline containing 20 minims each of brandy and aromatic spirits of ammonia administered. The latter was not retained it was repeated at midnight and again at 4 p.m. On these occasions it was partially retained.

At 8 a.m. the next day the Cheyne-Stokes breathing was very definite, temperature 100° F. and pulse still running. The child could not swallow water.

At 10 a.m. 2 ounces of saline with the addition of 1/2 minim liq. strychninae was injected subcutaneously. This was followed by a very definite reaction and at noon the temperature had risen to 103° F. The child was then able to swallow a little water. The injection was repeated at 4 and at 9 p.m. and though the cerebral control over the breathing was still inhibited the temperature remained at 103° F. during the day and the length of the Cheyne-Stokes cycle increased to 16.

By the following morning the child was able to take the breast which had been massaged and the milk flow improved. The temperature was now about 102° F. and the Cheyne-Stokes cycle about 30. The breathing gradually became normal and by 4 p.m. after forty-four hours of Cheyne-Stokes respiration had become quite regular. The temperature fell steadily, and five days after admission became normal.

Apart from flatulence which was controlled by small doses of salol the infant made an uneventful recovery, and on the tenth day after admission was discharged. It was then feeding and sleeping normally and the mother had a full supply of milk.

As there is no reason to suppose that the preparation given had not been well boiled and was therefore sterile, it would seem that the child was suffering from an auto-infection which was the cause of the medullary centre being depressed.

A. J. WATSON, M.B., B.S. Dunelm

Leikhoi, South China

ACCESSORY MAMMILL

A CHINESE woman, aged 25, complained on the second day of her puerperium of two painful swellings situated in either axilla. She stated that she first observed them when 15 years of age, they were then the size of a hazelnut. She consulted a doctor, who diagnosed them as "tumours," presumably lipomata, and no treatment was suggested. As they pained her at regular intervals she went, two years later, to a hospital, where a similar diagnosis was made and their removal was offered, operation was refused.

I found over each of these swellings an accessory nipple, and was able to express a small quantity of milk from each. In the following days the production of milk in both normal mammae was superabundant, and they required support. The accessory mammae shared in this full lactation, were freely secreting, and painful. It was felt that belladonna plasters were contraindicated lest normal and accessory mammae might communicate, and the mother so lose her milk or atropine be administered indirectly to the baby. It was hoped that involution would occur as a result of no demand being made upon their function if they were independent, and this has now taken place to some extent, although milk can still be squeezed from either.

These accessory mammae are perfectly formed, hemispherical, each superficially $\frac{3}{4}$ inches in diameter (the normal mammae are 7 inches). They are symmetrically situated upon the anterior border of each axilla. The nipple is centrally placed, three-eighths of an inch in diameter.

Reports of Societies.

AUTO-INFECTION IN NEUROLOGICAL LESIONS

A MEETING of the Edinburgh Medico-Chirurgical Society was held on June 3rd, with Sir DAVID WALLACE, President, in the chair.

Dr CHALMERS WATSON showed two cases of disseminated sclerosis to illustrate some of the points of his communication—The role of auto-infection or auto-infection in the etiology of disease of the higher and lower nervous systems.

The first case was a patient whose illness had lasted ten years, commencing with pruritus affecting the soles of the feet, gradually spreading up to the elbows and thighs, and later affecting the small of the back. This condition remained stationary for a year or two. Later she developed some insensitiveness and certain brain symptoms, but improved after a time in hospital. Now she had a recurrence of her symptoms showing Rombergism and a typical ataxic gait. Dr Watson wished to emphasize the importance of the general medical examination, to find out to what particular strain the patient had been subjected. In many cases the condition which this patient showed was found. She suffered from pronounced pyorrhea and constipation of the seven to eight day type. The urine, in accordance with Dr Watson's experience of most of these cases, was comparatively normal—free from albumin and sugar and practically free from bacteria. The other patient was an ex-serviceman who was perfectly healthy up to the time he contracted a severe dysentery. His signs showed a good deal of disturbance in co-ordination. He had a marked gastro-intestinal lesion, and a specially prepared vaccine produced distinct improvement.

Dr Watson drew no particular conclusions from these results except that they were interesting and stimulating, but his reason for showing the cases was to emphasize the association of these physical disorders with these neurological lesions. He referred to the view of French alienists of a hundred years ago, that mental disorders had their origin in abdominal disorders. This teaching had been largely disregarded, and though neurologists had added much to their knowledge of the symptoms and minute anatomy of disorder of the lower nervous system, corresponding advance in the knowledge of etiology and treatment had not been made.

Dr Watson referred to his views as published since 1900, on the factor of auto-infection taking origin in one or other of the mucous surfaces of the body—for example faulty state of teeth and gums, abnormal conditions of the digestive tract as revealed by physical examination, examination of the stools, and x-rays, and abnormalities in the urine, more especially the presence of bacteria and cells. He referred to the recent work on disseminated sclerosis, and to the conclusion tentatively drawn by experts from it, as to the intestinal tract being the primary source of the toxic agent responsible for the changes in the nervous system.

Dr ROBERT ROBERTSON agreed that in early cases of disseminated sclerosis something could be done for patient by studying their cases from a general point of view. Dr Chalmers Watson indicated. He recounted several cases in which removal of septic foci produced considerable amelioration in the nervous system symptoms.

Tryparsamide in Syphilis of the Nervous System

Mr DAVID LEES then read a communication—a preliminary note—on the use of triparasamide in the treatment of syphilis of the nervous system. He referred to the composition of the drug and to the fact that it was not a powerful treponemacidal agent, its use in the treatment of syphilis being based on other considerations: (1) a powerful stimulative effect on animal economy and on animal resistance, (2) a high degree of penetrability, and (3) a fair or moderate degree of treponemacidal action which, on account of the unusual penetrability of the drug, was equally available for therapeutic purposes in all parts of the body. Mr Lees said that in the beginning of 1924, by the aid of the Medical Research Council, he was able to commence the treatment of five patients, and up to now eighteen patients had been treated by this drug. All the patients suffered from syphilitic infection of the central nervous system, and showed both positive serological reactions and positive findings in the cerebrobiology of the spinal fluid. With few exceptions all had been intensively treated with salvarsan, mercury and iodides, and other forms of treatment, but none of them had shown that amount of clinical or serological improvement in their spinal fluid which justified any hope for any permanency as a result of this treatment, prolonged in some cases for three or four years. The drug was given intravenously in doses ranging from 2 to 3 grams weekly, the former being the initial dose. Mercury or bismuth was also given. Triparasamide was definitely contraindicated in patients with optic atrophy or other disease of the optic tract or albuminuria. No grave constitutional effects were produced. The immunity to disturbance of the liver was noticeable. One patient had severe jaundice under arsenobenzol. So far he had had 90 grams triparasamide and had shown no evidence of liver trouble. As a result of the treatment the general condition of most of the patients was markedly improved. They developed a sense of well-being, their cerebriation improved, and their power of application to work increased. The most marked change was in the cerebrospinal fluid. The cell count decreased in all cases. The amount of globulin progressively decreased. The cerebrospinal fluid under the Wassermann test became completely negative in three cases within a comparatively short period, averaging three months. Lange's gold sol test showed a marked improvement in every case. Mr Lees said that so far as he had been able to evaluate the drug it seemed to be specially

valuable in meningo-vascular syphilis, in early tabes, and in early general paralysis. It did not seem to retard or control advanced paresis. It did not appear to influence the blood Wassermann reaction to any appreciable extent, and so it would appear that adjuvant treatment with salvarsan and bismuth should be given. Mr. Lees showed six cases to illustrate his paper.

EDINBURGH OBSTETRICAL SOCIETY

At a meeting of the Edinburgh Obstetrical Society held on June 10th, the President, Professor B. P. WATSON, in the chair, three interesting papers were communicated to the Fellows.

Professor J. A. KILGORN (Dundee) described a case of abdominal pregnancy secondary to tubal gestation, operated on by him after full term. The case was of interest as there were no abnormal signs during pregnancy, and it was not until the patient was going to the maternity hospital thinking she was in labour that she collapsed and fainted, and was admitted to hospital in a serious condition. The condition was diagnosed and the abdomen opened forthwith. On opening the sac fetal gas escaped, followed by a gush of about two pints of chocolate-coloured fluid, and a dead, but not macerated, foetus weighing 5 lb. was delivered. The placenta was easily peeled off with little bleeding, showing that the foetus had been dead for some time, though it was in a good state of preservation. The sac could not be removed owing to adhesions, and it was plugged with a Mikulicz tampon, which was removed in forty-eight hours. The patient made an uneventful recovery. The probability was that the gestation had occurred in the right tube, and had gradually eroded the upper wall and had passed with membranes intact into the abdominal cavity. Spurious labour probably had occurred one month before operation, as foetal movements had ceased at that time and there was a history of slight pain and uterine haemorrhage then, the sac had become infected later.

Dr. DOUGLAS MILLER described his impressions of a visit to certain American and Canadian obstetrical and gynaecological clinics. As most of the chief cities had been visited in Dr. Miller's two months' stay across the water, his impressions were of great interest, especially when he came to discuss the various hospitals and their regimes and compared them with those in this country.

Dr. GIFFORD KENNEDY described a case of unusually slow foetal heart beat (80 a minute), which continued during a long first stage of labour and during the second stage also, but on delivery the child was found to be absolutely healthy, and nothing abnormal could be elicited on auscultation of the heart after birth.

At the annual general meeting of the Chelsea Clinical Society held at St. George's Hospital, Dr. GORDON LANE, the retiring president, opened a discussion on Facultative diagnosis. By this expression he meant the employment of the practitioner's powers of clinical diagnosis without resort to laboratory assistance. He thought that perhaps too much reliance was placed upon certain methods of diagnosis without using that power of observation that was inherent in everyone, to a greater or lesser degree. This was, perhaps, especially the case in the diagnosis of functional derangement of the ductless glands. Dr. C. O. HAWTHORNE laid stress on exact clinical methods, but was strongly in favour of describing what was observed, and being very exact in the deductions which were to be made logically from those observations. Messrs. FITZWILLIAMS, FORBES, A. R. THOMPSON, and Dr. CREWDSOM THOMAS took part in the discussion which followed.

At a meeting of the London Dermatological Society held at St. John's Hospital, Leicester Square, on Wednesday, June 17th, the annual oration of the society was delivered by Professor Dubreuilh of Bordeaux on Chronic sunburn and epithelioma of the skin. The annual dinner was held at the Frodoeur Restaurant, Professor Dubreuilh being the guest of the society.

Reviews.

TUMOURS AND CANCERS

If a philosopher, a physician, and a biologist agreed to co-operate in writing about cancer they would, it might be expected, produce a book of an unusual pattern which, if the co-operation were close, might resemble Mr. HASTINGS GILFORD'S *Tumours and Cancers*.¹ The closer the co-operation of the three hypothetical authors of the hypothetical book, the more striking would be the resemblance of their product to the volume Mr. Gilford has produced, for in it we meet the philosopher, physician, and biologist in every page and every paragraph.

The title of the book gives no indication of its distinctive character, and even the qualification "A Biological Study" adds little to satisfy the curiosity awakened by a glance through the table of contents. Here we notice that the volume is divided into eight books, whose titles are—"Introduction, growth and overgrowth," "Development," "The origin of cancer," "Nature and natural history of cancer," "The cause of cancer," "Cure and prevention of cancer," "Retrospect and prospect." Those who take the plunge to find what it is all about will have to wade to a good depth before their curiosity is satisfied, and it may perhaps happen that, even after reading Books V and VI on the natural history and cause of cancer, they will not find it easy to say in a few sentences what they have learnt.

To understand Mr. Gilford's views about cancer we must first appreciate the sense in which he uses the word "development" and its distinction from "growth." "Growth is a quantitative change with no reference to quality. To develop, on the other hand, is to become more intricate, to advance in complexity or quality. Though a thing may grow it does not necessarily develop, and though it may develop it need not grow" (p. 32). "Development either makes for progress or is regressive, with a tendency to work back in the form of a *reductio ad antiquum*. Regressive development is but another name for degeneration" (p. 77). He looks upon development, therefore, as first a progressive and later a regressive change, it is essentially a circular movement, "beginning with integration from inorganic elements and ending in disintegration into inorganic elements" (p. 627). Mr. Gilford looks on cancers as variations of the regressive development of single cells or cell groups, whereby they become quasi-embryonic and proliferate. Elsewhere the biologist in him speaks of cancers as composed of cells which have been stopped in their upward development, and as a consequence unduly hastened in their downward development. When the physician enters, cancer is referred to as "Nature's punishment for a biological crime", and when the philosopher steps forward he refers to cancer as the "captain of the degenerations," a motley company which includes defective intelligence, imbecility, idiocy, insanity, diabetes, tabes dorsalis, dementia, epilepsy, neurasthenia, alcoholism, and others. All such degenerations are, the author holds, becoming more common as civilization advances.

Such are some of the distinctive ideas of the book. We do not quote these passages as standards by which the book should be judged, but mention them as indicating its general character, in the hope that what we have said may invite others to study it for themselves. It is stimulating matter to read, because on almost every page some provocative idea or some startling generalization is to be met. In particular, Book III deserves special recommendation, for this scholarly and philosophical essay on normal and premature development is a masterly exposition of a difficult chapter in biology. Having said so much in praise, we feel compelled to draw attention to one fault: the book is unconscionably long. It ought to be read through without too much interruption if the thread of the argument is not to be lost, but how many readers will have the leisure or perseverance to continue faithfully to page 700? If

¹ *Tumours and Cancers*. By Hastings Gilford F.R.C.S. With an introduction by Sir Frederick Keeble (B.L. Sc.D. F.R.S. London: Selwyn and Blount Ltd. 1925. (Roy. 8vo. pp. xii + 703. £2 2s. net.)

repetitions had been avoided all the information might have been given in perhaps half the space. If Mr Gilford finds that this imposing book does not reach so many busy people as he wishes, it is to be hoped that he will offer the medical world a more compact and less expensive statement of his views.

PROBLEMS OF PERSONALITY

A STRINGS of studies by well known American, English, French, and Swiss psychologists has been published in a volume entitled *Problems of Personality* as a tribute to the pioneer work of Dr Morton Prince in the sphere of psychopathology. In his early years Dr Prince wrote a number of papers on general medicine and neurology, but he soon began to take a special interest in abnormal psychology. The *Dissociation of a Personality*, in which the complex disintegrations of an hysterical case are portrayed and interpreted, is probably his best known work, and it is interesting to note that he was writing on hypnotism, post-hypnotic suggestion, automatic writing, and double personality in 1890, at about the time when Pierre Janet published his famous work, *L'Automatisme Psychologique*, in which states of mental dissociation were made the subject of psychological investigation. Dr Prince has undoubtedly done much to arouse interest in a previously neglected sphere of medicine, and he has well deserved the respect paid to him which has now found tangible expression in the publication of this volume.

The studies included in the volume are written by workers in both abnormal and normal psychology, and the subjects chosen by the various contributors naturally cover a wide range. As might be expected, many divergent points of view are expressed, and some of the essays are polemical in tone. The book certainly reveals the extent to which psychology and psychopathology are lacking in that coherence and unity which is found in other branches of science, but its contents indicate that considerable advances have been made in the understanding of the human personality since the days when Dr Prince began his investigations. There is much in this work which the psychopathologist will find of interest.

PATHOLOGY

DR LUDWIG ASCHOFF, professor of pathological anatomy at Freiburg University, has published a series of lectures which he delivered in the United States during 1924, in a book entitled *Lectures on Pathology*. He appears to have travelled from one medical school to another, delivering memorial lectures and addressing medical societies, fourteen of these lectures are gathered together in this volume. The first is on the reticulo-endothelial system of the body, a theme on which Professor Aschoff can speak with paternal authority, for it was he who, in 1913, first proposed this designation for the reticulum cells of the splenic pulp and lymphoid apparatus and the reticulo-endothelial cells of the lymph nodes, blood sinuses of the spleen, capillaries of the liver lobules, bone marrow, adrenal cortex, and hypophysis. He proposed this name because these cells have in common the function of producing reticulum and of lining sinusoid blood and lymph spaces, they act simultaneously as lining endothelial cells and producers of reticulum. That this conception of the reticulo-endothelial system was correct, and the introduction of a new phrase justified, has been supported by the results of many careful studies in microscopical anatomy, and the term "reticulo-endothelial system" is coming into general use. Professor Aschoff's lecture is concerned chiefly with the significance of the reticulo-endothelial system in blood destruction, blood production, and general metabolic functions. The first lecture makes its chief appeal to the histologist, the second, on the pathogenesis of human pulmonary tuberculosis, to the physician, and the fourth, on pathological fatty changes,

will be welcomed by the biochemist. In fact, Professor Aschoff has something to say to nearly everybody, as a bare mention of the titles of the remaining lectures will show. Of these the more important are those on the morphology of the suprarenals, arterio-sclerosis, ovulation and menstruation, the origin of gall stones, the site and formation of bile pigment, the goitre problem, and renal secretion and renal disease. Dr Aschoff in his preface acknowledges his indebtedness to "various gentlemen" who translated the lectures and assisted in their preparation for publication, and he has been fortunate in their help, for the book reads easily without reminding us that it has been translated from another tongue.

Pathological Technique by Dr F. B. Mallory and Dr J. H. Wright, has long been a popular book with laboratory workers, and has now reached an eighth edition. It was first issued in 1897 as a practical manual for workers in pathological histology and bacteriology, has grown with the times, and has been built up into a rather expensive but almost indispensable book of reference. For the information of those who do not know the book we may say that it covers the whole field of practical pathology, having sections on histological methods, culture media, microscopical examination of bacteria and fungi, animal parasites, serological technique, and post mortem examinations. The main differences those familiar with previous editions will notice are that the chapter on blood has been rewritten and now presents both the technique of examination and the clinical interpretation of results, that the divisions devoted to bacteriology and serum diagnosis have been enlarged, and that brief directions have been added for photomicrography and the photography of gross pathological specimens. The book has grown to more than 660 pages, with 163 illustrations.

OPERATIVE SURGERY

THE fourth volume of Dr W. S. Bickham's treatise on *Operative Surgery* deals with thoracic and abdominal surgery and maintains the even and high standard of its predecessors. The descriptions of the operations, which are on the same plan as in the previous volumes, are detailed and alternative methods are given. On the whole the work is written on conservative lines—that is, methods which have been tried and tested are explained, and although it is well up to date the text has not been allowed to digress into controversial matters. On the big subject of gastric surgery the author quotes mainly the work and methods of the Mayos, Moynihan, Billroth, Balfour, and Kocher, and for statistics draws largely on the work of the Mayo Clinic. How recent the statistics with reference to Rammstedt's operation for congenital hypertrophic stenosis are it would be interesting to know, as the average mortality quoted is about 18 per cent. Perhaps the most disappointing chapter, especially in a book of this kind, which must be mainly one of reference, is that on the surgery of the spleen. Here we find little allusion to the "medical" spleens and their relation to splenectomy. The chapters on the biliary apparatus and intestinal surgery are good in that the illustrations are chosen with special reference to the display of operative technique. In the earlier chapters Trendelenburg's operation for embolism of the pulmonary arteries is described, and also three alternative methods of massage of the heart with their relative values are given.

The first section of the fifth volume is concerned with what is called the colo-recto-anal tract, in it are described the various modifications of the operations for colostomy, excision of the colon and rectum, colopexies and colopexions, haemorrhoids, fistulae, and the congenital abnormalities of these parts. It is surprising to find that, in

Pathological Technique. By F. B. Mallory, A.M. M.D. and J. H. Wright, A.M. M.D. S.D. Eighth edition revised and enlarged. Philadelphia and London: W. B. Saunders Company. 1924. (Demy 8vo pp. 666. 163 figures. 32s. 6d. net.)

Operative Surgery. By W. S. Bickham, M.D. F.A.C.S. Vol. IV and V and index volume. Philadelphia and London: W. B. Saunders Company. 1924 and 1925. (Roy. 8vo. Vol. IV pp. iii + 842. 773 figures. Vol. V pp. iii + 880. 1118 figures. Vol. V pp. iii + 842. 1224 figures. 50s. net. A volume £15 the set index volume free. Sold in complete sets only.)

dealing with the question of hemorrhoids, injection with carbolic acid is not mentioned. The major part of the volume is devoted to the genito-urinary tract, it contains a vast amount of information, and the author has not spared himself when dealing with such subjects as plastic operations on the ureters, operations for epispadias and hypospadias, and ectopic vesicle. The modifications described are legion. Textbooks are apt to slur over such subjects as the manner of using cystoscopes, urethrotomes, lithotrites, and evacuators, but here a very satisfactory account is given. In spite of the facilities afforded by ureteric catheterization, Lums's separator still maintains its hold on the textbook. Dr Bickham seems to have a partiality for Kelly's direct method of cystoscopy and ureteric catheterization in the female. It is difficult to understand why separate methods should obtain for the two sexes. If it is necessary to master the details of the cystoscope for the male, it would seem far simpler to apply them to the female as well.

The sixth volume, with a separate volume for the general index to all the volumes filling some 190 pages, brings to a close this vast compilation on surgical operative procedure. The sixth volume, after dealing with operations upon the ejaculatory ducts and prostate, proceeds to describe obstetrical and gynecological operations. The final chapter is devoted to deformities and disabilities of an orthopaedic nature not included in the earlier volumes. The operations on the prostate are very fully discussed, and the liter methods, such as partial prostatectomy by the intraurethral punch method, and transurethral prostatectomy by various criteria for prostatic obstruction, are described. The gynecological operations are fully detailed and illustrated, and special attention has been given to the numerous plastic devices which are employed in these regions. Where special instruments are required these are clearly illustrated. The midwifery section deals with delivery, version, Caesarian section, and the surgical treatment of the complications associated with pregnancy.

It must be with a great sense of relief that the author can survey the completion of his task. It has been an immense undertaking, and is thoroughly well done, but the volumes, it appears, are not sold separately, and how many surgeons will care to spend so large a sum as the publishers demand for a single book remains to be seen.

VOLUMETRIC ANALYSIS

SUTTON'S Volumetric Analysis has been a standard work for many years. The fact that it has passed through ten editions is substantial testimony of the appreciation in which it is held. The reason, we think, is not far to seek. It is a manual of technical chemistry as well as of volumetric methods. There are few chemical operations of a quantitative nature in which some attempt has not been made to subordinate them to a volumetric process, and few that cannot be made by one plan or another to yield trustworthy results in the hands of a practised operator. Some of these, it must be confessed, involve such cumbersome preparation that they are only useful when needed repeatedly, a single demand is more expeditiously discharged by a non-volumetric method. In many cases, however, there is no choice but to resort to some form of volumetric process. It is for these cases that the value of the work is inestimable. The new edition⁶ describes methods for the determination of a number of materials not treated of formerly and gives a large choice of methods for dealing with operations provided for in former editions. Published methods of procedure have been multiplied so extensively in recent years that there is a danger of some of the best being overlooked among the multitude and thus omitted from the mere lack of space to include all of them. Instances of such omission were inevitable, but the book has the saving merit of containing within a remarkably manageable space a most comprehensive collection of the directions and data needed for laboratory operations. From our first view of the

variety of subjects treated we expected to find a chapter devoted to methods for the chemical determinations employed in physiological laboratories, but none is the only physiological subject we found in the index. The text of the volume appears commendably free from error, and the quality of its contents will maintain the status which the work has so long held.

THROAT BIOPSIES

The term "biopsy" was introduced into dermatology by Darier to describe the excision and histological examination of a fragment of tissue from a lesion in a living patient in order to elucidate or confirm a diagnosis. Dr AMY has, in *Ja Biopsie Clinique en Oto-Rhino-Laryngologie*,⁷ elaborated in a substantial volume the application of this principle to oto-rhino-laryngology. The information gained by this means does not necessarily stop at the confirmation or correction of a diagnosis, because the more exact and detailed this is rendered by the aid of histological examination, the more accurate will be the prognosis and the more precise will be the indications for treatment, moreover, in certain cases the progress of the patient and the results of treatment can be checked by repeated biopsies. It is almost inevitable that in such a book the author should appear to claim too much for a particular method, but he quite frankly tells of its limitations, its failures, and of the harm that may follow if it be employed in unsuitable cases.

The exposition of the subject includes the histological as well as the clinical and manipulative aspect, and there are numerous excellent illustrations of the histopathology of the special regions concerned.

The book is overweighted with long case histories, and the author would do well on a future occasion to cut these down ruthlessly and devote even more space to illustrations and histological detail. The book as it is does infinite credit to the industry of the author and to the teaching in the clinic of Dr Lemaitre.

BOOKS FOR NURSES

We cannot always find space to review textbooks written for nurses, but we have received two which we think deserve to be brought to the notice of our readers because they are books which give in a plain and trustworthy fashion the sort of information which is necessary for a nurse's education in her work. The first of these, *Elementary Anatomy and Physiology for Nurses*, by Dr H. CLIFFORD BARCLAY, is a book which has already proved its usefulness, for it has run to a third edition.⁸ This well illustrated book explains the structure and function of the body in everyday language, and its teaching is made more easily assimilable because of the homely analogies with which the author explains his facts. Anatomy and physiology can only be rightly understood as sections of the larger subject of biology, a fact of which Dr Barclay frequently reminds the reader. "How can these dry bones live?" is a question which many a medical man preparing to lecture to nurses must have asked himself. A spark of physiology may light the fire, but plenty of biology is needed to feed the flames. Dr Barclay's book is well illustrated, and if the easy conversational style gives it a living interest to nurses we think that this success must be ascribed in chief to his wide biological outlook.

The other book, of larger scope, is the well established *Text-Book for Nurses* by Mr HENRY GROVES and the late Dr J. M. FORTESCUE-BRICKDALE. Since first published in 1912 this textbook has been in great demand, and fresh editions or impressions have been called for no less than ten times. The chief aim of the book, which deals with anatomy, physiology, surgery, and medicine, is to enable the nurse to understand the principles underlying the medical and surgical treatment which it is her duty to assist in carrying

Aubn. Preface de M. le Prof. Agrégé T. Lemaitre. Paris. Vigot Frères (Roy. Bro. pp. vii + 334. 39 figures. Fr. 30).

⁸ *Elementary Anatomy and Physiology for Nurses*. By H. Clifford Barclay. M.D. Ch.B. M.R.C.S. L.R.C.I. F.R.C.S. Edin. Third edition. London. Baillière Tindall and Cox. 1924. (Demy Bro. pp. x + 411. 49 figures. 12s. net.)

⁶ *A Systematic Handbook of Volumetric Analysis*. By Francis Sutton. F.I.C. F.C.S. Eleventh edition, revised throughout with numerous additions. By W. Lincoln Sutton, F.I.C. and Alfred E. Johnson, B.Sc. London. L.C.C. A.R.C.S.E.I. London. J. and A. Churchill. 1924. (Demy Bro. pp. vii + 629. 120 figures. 35s. net.)

wisely omitted. The medical section of the present third edition* has been revised by Dr J. A. NIXON and to this section a chapter on hygiene has now been added. We need say no more of the scope of the book than that it covers the syllabus prescribed by the General Nursing Council and provides a good basis for studying for the examinations by which a nurse's knowledge is tested.

While speaking of books for nurses we may mention a useful little pamphlet by Miss Louise KINGHAM, matron of the Weymouth and Dorset County Royal Eye Infirmary, entitled *The Nursing of Eye Cases*¹⁰. It will give a nurse a clear appreciation of the relative gravity of accidents to the eye, and enable her to follow intelligently the various ophthalmic operations at which she may have to assist.

NOTES ON BOOKS

THE volume on the lido ciliary diaphragm¹¹ is the second of a series of ophthalmological monographs written by Professor L. BRIEN of Paris. The first, dealing with the cornea and sclera, appeared about a year ago, the third, on the lens, is announced as in course of preparation. In the volume before us the author includes the whole of the uveal tract anterior to the ora serrata. After a summary of the anatomy and physiology of the structures concerned, the nervous and muscular anomalies of the pupil and ciliary body are dealt with in a very clear and comprehensive survey. This section is the most useful in the book. The remaining chapters deal with the diseases of the region seriatim—inflammations, wounds, neoplasms, congenital abnormalities, sympathetic ophthalmia and glaucoma are also considered as being diseases peculiarly associated with the part in question. The monograph is clearly and concisely written, it is authoritative rather than discursive, it does not enter largely into detail, and never becomes overburdened. The illustrations are numerous, but some of them lack clarity.

The relations of dermatology to general medicine are illustrated in two short essays—on the relations of eczema to internal diseases¹² by Professor S. EHRMANN, and on the relation of the genital organs to changes in the skin¹³ by Dr K. WIENER—both forming part of the series of monographs edited by Professor Jadassohn of Breslau and Professor Pinkus of Berlin. After definition of the term "eczematous diseases" Professor Lührmann discusses the occurrence of eczema in various metabolic diseases, such as diabetes, the urea acid diathesis and nephritis, and then considers the subject of eczema of the outflow of the alimentary canal and genito-urinary tract. The final chapter is devoted to the description, diagnosis, and treatment of the condition variously known as eczema nummular, neurodermatitis circumscripta, and lichen circumscriptus chronicus (Vidal). Dr Wiener's study deals with the various dermatoses associated with puberty, menstruation, pregnancy, labour, and the puerperium, as well as those attributed to diminution, absence, or pathological increase of the activities of the sex glands. A bibliography of recent literature is appended.

The *Synopsis of Medical Terminology*,¹⁴ by Dr M. J. SEIFERT, is a short dictionary of medical terms. It will be useful to students seeking the meaning of technical terms, and, we hope, a guide to anyone who may be labouring under a desire to coin a new word. To previous generations, well grounded in the classics, this book would have been valued only by the forgetful but to-day, when many students commence their course with less knowledge of Latin and perhaps none of Greek, it is likely that such a dictionary will meet a larger need. The habit of analysing all scientific terms greatly simplifies the study of any subject but since most medical terms have their origin in the Greek and Latin languages this good habit often requires the aid of a dictionary.

* *Text Book for Nurses* by E. W. Hov. Grove, M.D. B.Sc. M.S. F.R.C.S. and the late J. M. Fortepene Brickle, M.A. M.D. Oxon. F.R.C.P. Lond. The Medical Section revised by J. A. Nixon C.M.G. M.D. Cantab. F.R.C.P. Lond. Third edition. Oxford Medical Publications. London: H. Milford Oxford University Press 1925. (Demy 8vo pp. xxvii + 645 223 figures 20 net.)

¹⁰ *The Nursing of Eye Cases* by Louise Kingham S.R.N. London: H. Milford Oxford University Press 1925. (Cr. 8vo pp. 16 1s net.)

¹⁴ *Synopsis of Medical Terminology*. By M. J. Seifert. A.B. M.D. F.A.C.S. New York and London: D. Appleton and Co. 1925. (Demy 8vo pp. 30 3s 6d net.)

for its punctual observance. This book, after some observations on the general principles of medical terminology, gives an alphabetical list of medical suffixes, followed by a similar list of word root and an alphabetical list of prefixes. It occupies only thirty pages and it would perhaps have been more convenient if the book had been bound in such a way that it could be slipped into a pocket instead of being destined for the shelf.

Under the somewhat sonorous title of *Hygienic Fundamentals of Food Handling*¹⁵ an unpretentious little book has been prepared by two American writers, CHARLES THOM and ALBERT C. HUNT. It contains much miscellaneous information often omitted from books on hygiene—about such subjects as the decomposition of eggs, the preservation of fermentable food, and the canning of fruit. On the other hand, it does not give a very good account of the common type of food poisoning due to the salmonella toxin. In this, as in other American books, *B. botulinus* occupies a much more conspicuous place among the agents which threaten danger to food than it does in English presentations of the subject of food poisoning. We cannot picture any one class of people to whom this book would be particularly useful, but we think that some bacteriologists and medical officers of health, whose duties bring them into touch with problems of the preservation of food, would find it useful for occasional reference.

PREPARATIONS AND APPLIANCES

Kharulphan

THE Kharulphan brand of novarsenobenzol is a preparation made by Messrs Burroughs Wellcome and Co. Snow Hill Buildings, I.C.1, for subcutaneous and intramuscular injection. Its special feature is its great solubility: it dissolves rapidly and completely in its own weight of water or saline. As regards its lack of irritant properties the manufacturers state that it can be injected subcutaneously with a minimum of discomfort to the patient. The activity of the drug has been tested biologically under the arrangements approved by the Board of Trade and the Ministry of Health. This preparation should be found of great value by medical practitioners, for novarsenobenzol can be administered in this form with a minimum of trouble both to the practitioner and to the patient.

Hexamine and Methylene Blue

Messrs Burroughs Wellcome and Co. put up in tablets a combination of 3 grains of hexamine with 1/4 grain of methylene blue. The purpose of this combination is to enhance the well known action of hexamine as a urinary disinfectant. Methylene blue has a well marked action as a urinary antiseptic and acts equally well in acid or alkaline urine, whereas hexamine only acts under the former condition.

"Vacacneum"

"Vacacneum" is a vaccine prepared from *Staphylococcus pyogenes* and *Bacillus prodigiosus*. It is recommended for non specific vaccine therapy. A complete treatment it is stated consists of eighteen injections at intervals of two days. The makers claim that this treatment produces beneficial results in a number of conditions particularly in tabes and asthma. The preparation can be obtained from Messrs H. R. Napp Ltd., 3, Clements Inn, London, W.C.2.

"Otalgan"

"Otalgan" is a 5 per cent solution of phenazono (phenyl dimethyl pyrazolon) in anhydrous glycerin. The preparation is recommended for instillation into the ear for the relief of otitis media. This preparation also can be obtained from Messrs H. R. Napp.

An Ultraviolet Lamp

A new lamp for ultra violet radiation or 'artificial sunlight' (to use a term which is becoming discredited) has been introduced by the Medical Supply Association Ltd. (167 185 Gray's Inn Road, London W.C.1). Its distinguishing feature is that the radiation is obtained from an arc burning one pencil of tungsten and the other of carbon though if a more rapid reaction is desired both elements may be of tungsten. The visible illumination with this lamp is of less intense quality than with mercury vapour but there is no doubt as to the effectiveness of the ultra violet radiation. The lamp in the design of which the firm had the assistance of Dr Percy Hall is well constructed. The arc is contained in a polished aluminium hood which is supported on a vertical stand and this is mounted on a non base with rubber tyred castors. It has been stated that the carbon arc is the more useful for general treatment while the tungsten arc has its advantages in local use, as in the treatment of sinuses and discharging gland. This apparatus provides for both general and local irradiations the latter by means of a localizing mask which fits in front of the hood and carries a quartz lens. An extremely easy mechanism provides for horizontal and vertical movements and for a rotary movement around the support, the procedure of striking the arc and adjusting the elements is scarcely less simple than that of operating an ordinary electrical switch. The lamp has, we are informed, been manufactured entirely at the firm's London works.

ROCKEFELLER MEDICAL FELLOWSHIPS.

GREAT BRITAIN

The Medical Research Council announces that it has awarded Rockefeller Medical Fellowships, tenable in the United States of America during the academic year 1925-26, to the following

DAVID CAMPBELL, B.Sc., M.D. Glas., Pollok Lecturer in Pharmacology and Therapeutics, University of Glasgow

WILLIAM NORMAN CRAIB, M.C., B.A. Camb., of Good Hope, B. Chir. Camb., House Physician, Guy's Hospital, London

MISS KATHERINE HOPE COWAN, M.Sc. Manch., D.Sc. Lond., Assistant in Biochemistry, University College, London

WILLIAM SIFONRIED DAWSON, M.A. B.M.Oxf., M.R.C.P., Senior Assistant, Maudsley Hospital, London

HOWARD WILLIAM FLOREY, M.B. Melb., B.A. Oxf., John Lucas Walker Student, University of Cambridge

ARTHUR DAVIN RITCHIE, M.A. St. And., B.A. Camb., Lecturer in Physiological Chemistry, University of Manchester

GEORGE PALLING WRIGHT, B.A., B.M.Oxf., Macgregor Student and Demonstrator in Histology, University College, London

Dr Craib, Dr Florey, and Mr Ritchie have been appointed on modified conditions, while holding scholarships or emoluments from other sources. Mr Ritchie's Fellowship is being held during a short period of work in Canada this summer.

EPSOM COLLEGE

The annual general meeting of the Governors of Epsom College was held on June 26th, with the chairman of council, Dr Raymond Crawford, in the chair.

The chairman said that he hoped this would be a memorable year in the annals of the college and one pregnant of far-reaching results. Increased support from the profession and others had enabled the council to face increased commitments in various directions. In its determination to attain the highest educational level, it had made substantial improvements in the pecuniary prospects of the masters. The year had seen the completion of the rebuilding of the chapel as a memorial to the masters and boys who fell in the war. The new chemical block, thought and talked about for so many years, was now actually in hand, and had been made possible by several generous bequests. The vacated space would afford much needed additional accommodation for classrooms and lecture-room, and for a natural history museum, much better than that they now had. The council was now in a position, by the munificence of a benefactress, to carry out a complete transformation of the existing library, and to make it far more attractive and serviceable to the boys than in the past. The chairman expressed the hope that similar help from some other quarter might be forthcoming towards the equipment of a museum worthy of a school that supplied so many recruits to scientific professions. £500 would solve all difficulties in that direction. Another need of the college was the leveling and extension of some parts of the playing fields, so that all the boys might play their games under more inspiring conditions. The bursar had secured an estimate for the work, which showed that it could be well done for £1,500. These things were beyond the capacity of the normal revenue of the college, which this year was bearing the cost of an extensive substitution of electric light for gas, and which would almost at once have to provide better washing and drying facilities in the Lower School and probably in the not distant future to undertake the centralization of a scattered and wasteful system of heating and hot water supply.

The chairman concluded on a note of gratitude to all who had helped them to their good subscribers, donors, and benefactors, to their organization of local secretaries, which he wished to extend far more widely, to the great medical institutions, the British Medical Association and *British Medical Journal*, the *Tanet*, the Medical Insurance Agency, and numerous Panel Committees, to Mr Gerald Stanley, who had established at his own expense a scholarship giving free education at the college, and to Mr Arthur Chudleigh, who had given to the chapel a silver-plated cross, six candlesticks and vases for the altar, and in which dish

He hoped that the generosity of all these might prove contagious in many quarters.

On the motion of Dr de Havilland Hall, seconded by Sir St Clair Thomson Dr Raymond Crawford was appointed a vice president of the college in recognition of the fact that he had collected over £1,000 for the Royal Medical Foundation attached to the college.

Pensions and Scholarships

The scrutineers, Dr E. Climson Greenwood, Dr Raymond Crawford, and Sir William Hale-White, reported the successful candidates to be as under

Pensionerships	Votes

MENTAL INVALIDS

THE Moulton Lectures for 1925 were delivered in the Royal College of Physicians, Edinburgh, by Dr C. C. Easterbrook, Physician Superintendent of the Crichton Royal Institution, Dumfries, on June 22nd, 24th, and 26th. He took as his subject "Mental invalids."

The Body-Mind

In the first lecture, on the "Body-Mind," he dealt with the conception of the biopsychic nature of the human organism in health, in bodily disease, and in mental disease. He maintained that the integration of the various parts of the organism into a working unit had been effected by the nervous system at gradually ascending levels of its activity corresponding to the phylogeny of man's adjustment with environment, and was represented from below upwards by the vegetative, sensorimotor, and mental provinces of the nervous system. The first of these in its sympathetic and autonomic parts integrated the biological machinery of metabolism, growth, development, and decay, and differences had to be recognized between sympathetic-tonic and autonomic individuals. The sensorimotor nervous system integrated the motor machinery of the body and its parts, and recent work on the constitution and innervation of the skeletal muscles showed that this part of the system had a bearing on the peripheral explanation of the genesis of emotion. The mental nervous system integrated the mental machinery of the body and its parts, subvocal conscious and unconscious mental activity, and its highest level in the cerebral cortex, unified and expressed the individual, put him in relation with his environment, and regulated his conduct. Consciousness—that is self-consciousness—was to be explained by stimulation of the cerebral cortex from within or from without the body. With regard to unconscious mental activity, man's origin of mind must be regarded as coextensive with his body. The new psychology stressed the importance of feeling, desire, and instincts in human mentation and conduct, and lowered the influence of reason, moral sense, will, and self-control, the higher qualities of mind which distinguished man from animals and had made him the master. The lecturer observed that the terms of physics and chemistry were inadequate in biology, and still more so in psychology, for the terms of each science had their own distinctive meaning, and in man biological and psychological occurrences were unique.

* See BRITISH MEDICAL JOURNAL, February 28th 1925 p. 422.

Clinical Examination, Causation and Prevention of Mental Diseases

In the second lecture Dr Easterbrook dealt first with the clinical examination of mental invalids, and detailed what he considered to be in ideal form of clinical record. He then went on to consider the causation of mental diseases and their prevention. He expressed the opinion that it was better to regard the two great factors productive of mental disease as a nervous constitution, inherited or acquired, which was a predisposing factor, and stress, which was an exciting factor, rather than, as was commonly done, to speak of heredity and stress. The nervous constitution, inherited or acquired, was the essential causal basis of a mental breakdown, and it was very important that it should be recognized by the individual. The sources of evidence of this constitution were six in number—namely: (1) The presence of some congenital nervous, mental, or moral defect. (2) The occurrence in previous life from infancy onwards of some acquired psychosis, psychoneurosis, or neurosis. (3) The occurrence in earlier life of periodic or persistent morbid tendencies—that is, faulty habits and vices. (4) The presence of an abnormal temperament, either inherited or acquired, which was the most frequent and the most subtle sign of a nervous constitution and specially important to recognize, this might include the unusual development of such qualities as irritability, jealousy, waywardness, optimism or pessimism, etc., or it might take the form of an abnormal conflict between the instincts of the "herd" and of self-preservation. (5) The presence of a nervous or degenerate physiognomy and physique had to be considered, but, in the lecturer's opinion, this was apt to be artificial, and was not of great importance. (6) A family history including the occurrence of mental and nervous diseases and of morbid disposition and habits among the individual's nearest blood relatives. Dr Easterbrook classified the various stresses or exciting factors which might produce mental disease in seven classes, which included direct pathologic stresses involving diseases of the nervous system, indirect pathologic stresses involving bodily disease, metabolic disorders, and endocrine disorders, toxic stresses such as the action of alcohol, cocaine, lead, etc., on the nervous system, energetic stresses, which included external agencies producing shock, exhaustion, and poisoning of the nervous system, hygienic stresses, including privations or excesses in mode of life, biologic stresses, including abnormal changes occurring in the organism during the mental and reproductive epochs and crises of life, and psychic stresses, including excessive mental perturbations, such as prolonged worry, and privations, such as solitude and want of occupation.

Classification of Mental Diseases, Curative Treatment

In the third lecture Dr Easterbrook dealt with the classification of mental diseases, and added some remarks on methods and aspects of curative treatment. He proposed a nosological classification of mental diseases by which they were divided into the congenital psychoses, such as mental defectiveness in its various grades, and the constitutional psychoses, which included melancholia, confusion, dementia, delusional insanity, and the psychoneuroses, etc. He pointed out that the great autonomic feature of these disorders was chromatolysis of the cortical cells, which became unduly worn out, and of which numbers disappeared, the organic psychoses included conditions such as cerebral sclerosis, haemorrhage, tumour, and other gross nervous lesions, the organismal or "bodily" psychoses included a great number of infective and other bodily diseases which produced an indirect mental effect, the toxic and energetic psychoses included the influence of drugs and the various energetic traumas. The lecturer next considered some aspects of curative treatment. He pointed out in the first place the great importance of the movement which was at present taking place for the voluntary admission of patients to asylums. In 1900 the number of voluntary private patients admitted into the Royal and District Asylums in Scotland had been 84 while in 1924 the number had risen

to 431. This was of special importance in regard to the early treatment of mental disease. He considered that no general hospital or medical school could be regarded as complete without its psychiatric clinic. He attached great importance to the open air rest treatment in active psychosis, and showed plans of buildings specially adapted for this purpose. In regard to endocrine therapy, it had, he said, been found that most glandular extracts in all probability acted simply because of their large nucleoprotein content, and without reference to the particular gland from which they were derived. Thus, however, did not apply to thyroid extract which in large doses continued for a week, produced a marked catabolic effect with loss of weight, when the thyroid administration was stopped at the end of a week, a marked anabolic rebound took place in which the patient not only gained quickly in weight, but in which the mental symptoms were likely to disappear, thus greatly shortening the period of treatment.

THE HEALTH GOVERNMENT OF GERMANY

The League of Nations, in continuance of its policy of giving information to its constituent members in matters of international importance, has issued two statements on the subject of public health services, one relating to Germany, the other to Austria. They have been prepared, the former by Dr. Gottfried Levy, medical director of the central health office in Berlin, and the other by Dr. Hermann Schloetter. The pamphlets, which contain 60 and 80 large octavo pages respectively, would have been much the better for tables of contents. The subjects dealt with include notification of infectious diseases, the procedure for their investigation, the periodic publication of statistics, the registration of births and deaths, public health legislation and sanitary organization, sanitary equipment, hospitals, sanatoriums, lunatic asylums, etc. the campaigns against tuberculosis and venereal diseases, the protection of maternity and of babies and children, housing, water supply, and drainage, and, finally, the control of foodstuffs. Germany is a federation of eighteen States which possess the right of enacting their own laws, so long as the central authority (Reich) does not use its legislative power.

Notification of Disease and Registration of Death

The reader will find many differences between German and English administration. Notifications of infectious disease are made to the police authorities, and by them are forwarded to the district medical officer, any change of the place of residence of an infected person must be intimated to the police of both areas. In puerperal fever the medical officer may only visit with consent of the householder, which, however, is seldom refused. Where anthrax, glanders, dysentery, or typhoid fever occurs the police may order an official post-mortem examination, "if possible by a doctor," before burial. The Reich has not yet adopted the international system of registering causes of death. The birth of a stillborn child must be notified on the following day to the registrar. Illegitimate births must be notified within a week by attending midwives. A stillbirth is defined as one in which no pulsations of the heart are observable after issue from the womb. As regards deaths in general, "the accuracy of entries in the annual 'causes of death' is in the main ensured by the fact that these statistics extend to all the towns, in which medical post-mortem examination is generally compulsory." Registration, however, is done by non-medical persons, and apparently a medical certificate is unnecessary, in some places post-mortem examinations may be made by barber surgeons or "layers-out." Statistics are given for various States showing that in 25 to 30 per cent of fatal illnesses there was no medical attendance.

Health Officers

Candidates for appointments as State health officials must follow a specified course of study and examination. The subjects include forensic medicine, psychiatry, social hygiene, pathological anatomy, and bacteriology. If a

candidato fails to pass any part of the examination he is not allowed to come up for re-examination more than once. "In Prussia it is a condition of appointment as Kreis (district) medical officer that the candidato should have worked five years as an independent medical practitioner after passing the examination." The word "after" will be noted in this quotation as indicating a conception and scheme quite different from that of this country. The same officer deals with public health and forensic medicine, and must have had considerable experience in general practice.

The English reader will find in the pamphlet a curious reminder of the old practice of affixing warning notices to houses in which there are cases of infectious disease. "The marking shall be in a conspicuous place and shall be in the form of a yellow signboard by day and a yellow lantern by night." These marks are required for typhoid fever and relapsing fever. The campaign against alcoholism occupies an important place in Germany.

In Germany the State authorities have always given the fullest attention to the social consequences of alcoholism—for example, the deterioration or destruction of efficiency, increased debility of health and mortality, undermining of family life, degeneracy in children and increased crime and vagrancy. The following measures have been taken by the Government: the establishment of a Reich monopoly for the production and sale of spirits entailing higher prices and consequently lower consumption; restriction of retail sale on dry days in certain highly industrialized districts; prohibition of the hawking of spirits, encouragement of the establishment of temperance hotels and of the production of non-alcoholic refreshing and stimulating drinks; licensing regulations, control of imports, general popular education, and lastly, legislative measures for placing drunkards under guardians or trustees and confining them in sanatoriums.

A considerable percentage of the surplus proceeds of the brandy monopoly (amounting to 20,000,000 marks in 1922) is applied annually to combating alcoholism and diseases consequent, such as tuberculosis and venereal diseases, to subsidizing the establishment of teetotal inns, young people's clubs, and dairies, to instituting training courses for juvenile welfare workers and officers of philanthropic societies and to educational work (anti-alcoholic exhibitions, touring lectures, etc.). In addition to the State administrations the large private welfare associations also receive considerable financial assistance.

The pamphlet contains information on many other matters of interest, not only to public health officers, but to students of sociology in this country. The pamphlet for Austria contains even fuller details.

Nova et Vetera.

THE SALERNIAN RULES OF HEALTH

To wander through what were formerly the abodes of splendour or renown is always a melancholy proceeding, but in no case is this more true than in the case of the modern Salerno. Here is a sleepy Italian town of some forty thousand inhabitants. Few people move in the streets, and those few seem in no hurry about their business. Though the town has no natural attractions in itself, its situation at the head of a bay bearing its own name is exceedingly beautiful. From the sea the ground slopes upwards and reaches to the height of small mountains a short distance away. The oldest part of the town stands on high ground and still retains houses dating back to the twelfth, to the eleventh, and even, it is said, to the tenth centuries. Certainly the cathedral dates from the year 1070 and contains sarcophagi which may yet retain the mortal remains of the Norman adventurers who conquered Apulia in the eleventh century. We search in vain for any remains of the once famous medical schools or hospitals, "while memory watches o'er the sad review."

It was in 1075 that Duke Robert of Normandy, while leading the French and Normans to a crusade, arrived at Salerno and remained during the following winter. The crusade was successful, but the Duke, having received a wound, returned to Salerno to be cured. Either the cure was tedious or dalliance in love caused him to spend a whole year in the town, and this long absence abroad may have largely contributed to his loss of the English crown and to his twenty-eight years' imprisonment.

Though its renown as a centre of medical education has

long since gone, Salerno will remain famous by reason of the poem in rhyming Latin verse entitled "*Regimen Sanitatis Salernitanum*." This was composed in honour of Duke Robert and presented to him in 1076. It was esteemed so highly that no fewer than 100 manuscripts still exist, and over 240 printed editions appeared between 1480 and 1846.

It is really a treatise on all matters relating to the preservation of health (*Conservandae Bonae Valetudinis Praecepta*), and though it contains the accumulated wisdom of the school the main part is thought to have been composed by John de Milano, who, indeed, in a manuscript of date 1418, is named as the author. It is written in a popular style, and in its original form was comparatively short, the edition of Arnould containing but 326 verses. Later writers have added to it to such an extent that the edition of M. Baudry de Balzac contains 2,300 verses, and that of Rienzi 3,520.

The following extracts have been made from the text of Arnould de Villa Nova, who lived close to Salerno in the thirteenth century, and it is this text which Sir Alexander Crooke published in 1830. It is much the same as that entitled "*Conservandae Bonae Valetudinis Praecepta* longo Saluberrima Regi Anglorum quondam a Doctoribus Scholae Salernitanae. The Salerne schoole or the Regiment of Health. That is Physiell Observations for the perfect preserving of the Body of Man in Continuall Health. Edinburgh, printed by Andie Hart, and are to be sold at his shop, on the north side of the hie Street, a little beneath the Crosso Anno domini 1613" (Black letter.)

The Salerno Schoole doth by these lines impart
All health to England's King, and doth advise
From care his head to keepe from wrath his heart,
Drinke not much wine, sup light and soone arise
When meat is gone long sitting breedeth smart
And after noone still waking keep your eyes
When moov'd you finde your selfe to Nature's needs,
Forbeare them not, for that much danger breeds

Use three Physicians still first Doctor Quiet,
Next Doctor Merri man and Doctor Dret

Long sleep at afternoon breeds slouth, agues and rhumes

Great harmes have growne and maladies exceeding
By leeping in a little blast of wind
So Cramps and Dropsies, Colicks, have their breeding
And Mized brames, for want of vent behind
Besides we find in stories worth the reading
A certaine Romaine Emperour was so kind
Claudius by name he made a proclamation,
A seapo to be no losse of reputation

Pears, apples, peaches milke and cheeso
Salt-meats, Red Deere Hart, Beefe and Goat all these
Are meates that breed ill blood and melancholy

Wine Women Baths, by Art or Nature warme,
Usde or abuse, do men much good or harme

Six things that here in order shall insue
Against all poison have a secret powre
Peares Garlick Radish roots Nuts, Triacle, Rew
But Garlick cheese, for they that it devoure
May drinke, and eat not who their drinke do brew,
May walk in aires infected every houre,
With Garlick then hath power to save from death
Beare with it though it make unsavoury breath
And scorne not Garlick like to some that thinke
It onely makes man winke, and drinke and stinke

Though all ill savours do not breed infection
Yet sure Infection cometh most by smelling
Who smelleth still perfum'd his complexion
Is not perfum'd by *Poet Martialis* telling
Yet for your lodging rooms give this direction
In houses where you munde to make your dwelling,
That nere the same there be no evill scents
Of puddle waters or of excrements
Let ayre be cleare, and light and free from faults
That come of secret passages and vaults

If wine have overnight a surfeit brought
Then early in the morning drinke a draught
And that a kind of remedy shall yield

(The poem then goes on to describe the kinds of wine and when they ought to be drunk.)

It in your drinke you mingle Rew with Sage
All poyson is expell'd by power of those,
And if you would withall lusts heat aswage
Add to the same the gentle floure of Rose

Would not be sick when the seas do rage
Sea water drinke with wine before he goes

Of washing of your hands much good doth rise,
'Tis wholesome cleanly and relieves your eyes

Some to drinke onely water are assign'd
But such by our consent shall drinke alone
For water and small beere we make no question
Are enemies to health and good digestion
And Horace in a verse of his rehearces
That water drinkers never make good verres

To show what liberties the translator has taken and how he has
do additions both here and elsewhere, the original runs

Potus atque sumptus sit edendi valde necesse
Infrigidat stomachumque cibum nititur fore crustum)

We see the better sort thereof [cheese] doth crite
To make as it were a period of their meat
The poorer sort when other meat is scant
For hunger eat it to relieve their want

To close your stomach well this order sutes
Cheese after Flesh Nuts after Fish or Fruits
Yet some have said, beleeve them as you will
One nut doth good two hurt, the third doth kill

Raw pears are heavy to digest we see
Drink after Pears, tines after Apples order
To have a place to purge yourself of ordure

Cool damsons are good for health by reason
They make your intestines soluble and slacke

By Figs are lice engendered, I must provoken

New Rennish wine stirs urine doth not blude
But rather loose the belly breeding wind

It [vinegar] makes one melanchol hurts their eyes,
Not making fat nor mending their complexion
It lessens sperme makes appetite to rise
But taste and scent is good against infection

Four special virtues hath a rop in wine
It maketh the teeth white it clears the eye
It adds unto an empty stomach fulnesse
And from a stomach full it takes the dulnesse

Good dyet is a perfect way of curing
And worthy much regard and health assuring

The wormes that knowes the wombo and never stint
Are kill'd and purg'd and driven away with mint
But who can write thy worth (O soveraigne worme)
Some ask how men can die while thou dost grow

Rew is a noble hearbe to give it right
To chew it fasting, it will purge the sight
One qualitie thereof yet blame I must
It makes man chaste and women fild with lust
Faire ladies, if these Physicke rules be true
That Rew hath such strange qualites as these
Eat little Rew lest your good husbands rew
And breede betweene you both a sinew disease
Rew whets the wit and move to pleasure you
In water boyld it rids a roome of fleas

For writers old and new, both ours and forren
Affirme the seed [of green willow] make women chaste and barren

If in your teeth you hap to be tormented
By meane some little wormes therein do breed
Which paine (if heed be tane) may be prevented
By keeping cleane your teeth when as you feed
Burne Frank incense (a gum not evil scented)
Put henbane unto this and Onyon seed
And with a Tunnell to the tooth that's hollow
Convey the smoke thereof and ease shall follow

Four humours raigne within our bodies who's
And these compared to foure elements
The Sanguin Cholier Flegme and Melancholy
The latter two are heavy dull of sense
The other are more joviall quick and joly
And may be likened thus (without offence)
Lyke fire both warme and moist is Sanguin deare,
Lyke fire doth Cholier hot and dry appeare
Lyke water cold and moist is Flegmatique
The Melancholy cold dry earth is like

The Sanguin gamesome is and nothing nyce,
Loves wine and women and all recreation
Lies pleasant tales and newes plays cards and dice
Fit for all company and every fashious
Though bold not apt to take offence nor usefull
But bountiful and kind and looking chearefull
Inclining to be fat and prone to laffer
Loves mirth and musick, cares not what comes after

(The poem describes the characteristics of Cholier as being
violent and fierce, ambitious, proud bountiful, often inebriate, a
right bold speaker and 'as bold a lark' easily roused to anger,
having a good appetite, 'yet ever looking pin'd')

In younger yeares they use to grow apace,
In elder hairy on their breast and face

The Flegmatique Most of no great growth inclining rather to
be fat and square lazy, not well educated, dreamy, or else still
spitting to avoid the flegme

The Melancholy Very studious and solitary person apt to be
hateful to others constant sometimes extreme in love, seldom
in love, mistaking, sparing, not daring

Now though we give these humours severall names
Yet all men are of all participant
But all have not in quantity the same
For some (in some) are more predominant

If Sanguin humor do too much abound
These signs will be thereof appearing chiefe
The face will swell, the cheeke grow red and round,
With burning eyes the pulse beat soft and briefe
The venes exceed, the belly will be bound
The temples and the forehead full of griefe
Unquiet sleepes that so strange dreames will make
To cause one blush to tell when he doth wake
Besides the moisture of the mouth and spittle
Will taste too sweet and scarce the throat to tickle

If Cholier do exceed as may sometime,
Your eares will ring and make you lo be wakefull
Your tongue will scrape all rough and oftentimes
Cause vomit, unaccustomed and hatefull
Great thirst, your excrements full of slime
The stomach squeamish sustenance ungratefull
Your appetite will sceme in nought delighting
Your heart still grieved with continuall bying
The pulse beat hard and swift all hot extreme
Your spittle sowie, of firewore oft your dreames

If Flegme aboundance have due limits past
These signes are here set downe will plainly shew
The mouth will sceme to you quite out of taste
And apt with moisture still to overflow
Your sides will sceme all sore down to the waste,
Your meat war bothsome, your digestion slow
Your head and stomach both in so ill taking,
One reeking ever gipping t'other raking
With empty venes the pulse beat slow and soft
In sleep, of Seas and Rivers dreaming off

But if that dangerous humor over raigne
Of Melancholy sometime making mad
These tokens then will be appearing plaine
The pulse beat hard the colour darke and bad
The water thin a worke fantastick blaine
Irris grounded jo or els perpetuall sad
Affrighted oftentimes with dreames like visions
Presenting to the thought all apparitions
Of bitter belches from the stomach coming
His crye (the left especiall) ever burning

To bleed doth cheere the pensive and remove
The raging furies bred by burning love

Make your incision large and not too deepe
That blood have speedy issue with the fume
So that from sinnewes you all hurt do keepe
Nor may you (as I taught before) presume
In sixe ensuing houres at all to sleepe
Lest some slight blisse in sleepe cause an apostume

First in the Spring for quantity you shall
Of blood take twyce as much as in the Fall

In Spring and Summer let the Right Arme blood,
The Left and Winter for the left are good
The Heart and Liver Spring and Summer bleeding
The Left and Winter hand and foot doth mend
One vein cut in the hand doth helpe exceeding
Unto the spleene voyce breast and intrals lend
And swages griefes that in the heart are bleeding

The Translator to the Reader

But here the Salerne school doth make an end
And here I cease to write but will not cease
To wish you live in health and out in peace
And ye our Physick rules that frindly read
God grant that Physick you may never neede

These few extracts will show the scope and intention of
the poem and that it was well suited to the needs of the
time in which it was written is evident

CANCER RESEARCHES

INVESTIGATIONS into the biochemical properties of the blood serum in disease, especially when they come to fruition and prove to be of practical service in diagnosis, are of interest to all clinicians. While still in the imperfect stage they are of even greater interest to laboratory workers, who may by their experiments and criticism develop a more finished and certain technique than had been foreseen by the individual who began the work. On the other hand, the play of instructed criticism may prevent the adoption into practical medicine of a jejune or a fallacious method. The sero diagnostic methods in cancer have been numerous and varied, but none so far has satisfactorily passed the test of reliability. Remembering the many attempts in the past, with their claims pitched high and their accomplishments so disappointing, we approach each new reaction with increasing scepticism if only it would exhibit a human amount of fallibility we should bid it a kinder welcome. Probably in most cases the organisms are aware of the clinical diagnosis before recording the results of their reactions (indeed, in working out the method this must be so at the beginning), and unconsciously they are biased in their interpretations, smoothing out the doubtful findings and dismissing or excusing the palpably adverse. The critical student, unimpressed by the reputed perfections of another's bantling, emphasizes the failures. Not infrequently, too the number of cases tested or recorded is much too small, or the sample of other diseases is too selected for the real worth of the reaction in practice to be estimated. Now and again a method is propounded which, from internal evidence, impresses the reader as worthy of trial.

We publish this week (p. 4) a communication by Dr. H. J. B. Fry of the Cancer Hospital Research Institute giving details of a sero diagnostic method of his own devising which seems to have been sufficiently well tested to be put before the critics, and for which the claims are modestly stated. It is a simple flocculation reaction that apparently gives sharp readings. The "antigens" (why cannot pathologists agree to use a more accurate designation?) have been prepared from mammary carcinomata, and are composed of the alcohol soluble constituents of the material from which substances soluble in saline and acetone have previously been removed. The alcoholic extract, fortified with cholesterol, is standardized and added to four dilutions of the inactivated serum under test. The tubes are incubated, and a preliminary reading is taken at the end of three hours, the final result being determined after twenty-four hours at room temperature. A positive result is indicated by the appearance of flocculi in the tubes. In a series of 500 cases, comprising malignant and non-malignant conditions, 75 per cent of correct results were obtained, positive results were obtained in 71 per cent of the cancer cases, and negative results in 78 per cent of the non-cancerous, while the serums of healthy individuals in all but one instance reacted negatively. The analysis of the results is interesting.

There are two rather surprising findings in the use of this method. Seeing that the "antigen," at least in its mode of preparation, so closely resembles that of Boidet and Ruelens used in the flocculation reaction for syphilis, it might have been imagined that syphilitic serum would be apt to give positive reactions, but when tested in parallel with the Wassermann reaction Dr. Fry's reaction did not seem to be sensitive in this respect. The latter depends on some other reacting substance present in the serum. The other unexpected feature is that the antigens prepared from the epithelial cell carcinomata of the breast reacted even better with serums from other malignant manifestations than they did with the serums of patients suffering from mammary cancer. In fact, a very low percentage of successes (58) was given by breast cancers, while epitheliomata, as of the skin, oesophagus, bladder, and cervix uteri, showed from 80 to 100 per cent of positive results. The antigen also gave satisfactory results with the serum from cases of sarcoma. Taking all the cases of malignant disease together, the results of this reaction are as good as those obtained by means of the Wassermann reaction in all cases of untreated syphilis. So much for the positive side. On the other hand, the reaction proved fallacious in about 20 per cent of the non-cancerous cases. Perhaps this figure is unduly high, for Dr. Fry has considered as non-cancerous all those cases in which a diagnosis of malignancy could not be established. The sensitivity of the reaction with tuberculous serums, in particular, is unfortunate, but, excluding this disease, the results of the reaction are very promising, and would seem to be very helpful in the diagnosis of clinically doubtful conditions. The further exploration of this reaction by Dr. Fry and others will be welcomed.

Another member of the staff of the Cancer Hospital Research Institute, Dr. E. L. Kennaway, contributes to our columns this week (p. 1) an important paper bearing on the problems of the etiology of cancer. He had previously¹ investigated various fractions of coal tar and compounds derived from tar in order to throw light on the chemical constitution of the cancer-producing factor. The finding of such a substance would have been much more than a mere laboratory triumph, for it might have afforded an insight into the unknown substances which, it must be supposed, are responsible for the induction of malignant processes in general; whether we admit that their function is exciting or merely predisposing. The analysis of coal tar, however, having proved disappointing in this respect, Dr. Kennaway has approached the problem from another aspect. From such compounds of known chemical constitution as isoprene and acetylene he has been able to prepare tar-like products of comparatively simple composition, containing no elements other than carbon and hydrogen, which have proved particularly effective in producing epithelioma when applied to mice. The influence of high temperatures on the formation of carcinogenic substances from coal and petroleum, so important industrially, led him to try if similar substances could be produced from previously living tissues. A tar prepared from yeast had the cancer-producing property. A distillation product from human skin also exhibited the same property. It is obvious that in the living body there cannot be such a crude process in action to produce from the tissues this carcinogenic substance, but it is not beyond the bounds of possibility that

¹ BRITISH MEDICAL JOURNAL, March 29th 1924, p. 564.

"the human skin may be capable of forming very slowly substances which, when required in bulk and rapidly, can *in vitro* be produced from skin only at a red heat" The hydrolysis and oxidation of fats and proteins which take place in the body can only be performed in the laboratory by strong reagents and high temperatures. In discussing the results he has obtained in these interesting researches Dr Kennaway dissents from the views of some critics that the carcinogenic agents, as established by the experiments at the Cancer Hospital, merely act because they are "irritants." There are irritants and irritants some may produce cancer, while many do not. The property of producing cancer is a special property, whether a substance possesses it or not cannot be determined from a knowledge of its chemical constitution or its immediate effect on tissues, but only from the slow, unintentional mass experiment on human beings, or, more directly and speedily, by the set experiment on lower animals.

CLASSIFICATION OF BACTERIA

ALL bacteriologists will agree that the time has come when more serious effort should be made to classify bacteria in a scientific way, but the difficulties of the task are enormous. The earlier classifications, based primarily on morphology, have proved unsatisfactory. Later, when the botanist stepped in to catalogue these tiny members of his extended kingdom, he neglected the physiological behaviour of too many of them, with the result that his cumbersome Latin titles found no favour with the practical bacteriologist. Meanwhile the philistine pathologist has been a flagrant offender in the eyes of the systematic biologist, because he has simply named his germ according to the disease it produces, and neglected the conventions of both botanists and zoologists. As a rule the biologist has only been interested in the bacillus and the pathologist in the disease.

We have been watching with great interest the labours the Society of American Bacteriologists has undertaken with the object of deciding on some acceptable system of classification. In September, 1917, appeared the preliminary report of the committee, presided over by Dr Winslow, on characterization and classification of bacterial types, and in May, 1920, the final report of the committee was published. In 1923 a committee of the same society prepared a manual of determinative bacteriology, which in general followed the classification suggested by Winslow and his colleagues. These publications constitute a notable advance, and should do a great deal to produce order out of the prevailing chaos.

We welcome a further contribution to the same subject from Dr R. E. Buchanan, professor of bacteriology at the Iowa State College.¹ He has written the first of a series of monographs on systematic bacteriology, to be published by the Society of American Bacteriologists. This is a book of close on 600 pages, devoted to the history of the nomenclature and classification of the groups of bacteria hitherto described. The first chapter is an historical account of the various classifications of bacteria that have been proposed. Thence he passes, in the second chapter, to a discussion of codes of nomenclature and their relation to the problems of bacterial terminology. The third and final chapter, which constitutes nearly

two thirds of the book, contains an alphabetical list of the names which have been proposed for subgenera, genera, subtribes, tribes, subfamilies, families, orders, and classes of bacteria, including casual or vernacular terms which have had more or less extensive recognition. Professor Buchanan has attempted with each name to give the original diagnosis of the term, to discuss its usage by bacteriologists, and to point out whether or not its use is legitimate. Wherever practicable the author has quoted the original description and discussed the comments of subsequent writers. Obviously the compilation of such a dictionary as this has necessitated an immense amount of study, and there is no doubt that it will be extremely useful as a guide to correct nomenclature.

CENTENARY OF THE HOUSE OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON

FOUNDED by Thomas Linacre in 1518, and therefore now in its fifth century, the Royal College of Physicians of London has had four homes, three of them close together in the neighbourhood of St Pauls—in Knightbridge Street (1518-1614), in Amen Corner (1614-1666), destroyed by the Great Fire, and in Warwick Lane (1674-1825). Its move in 1825 had been foreshadowed for some time by the alteration in the character of the neighbourhood, which had become "the wrong end of the town," and by the deterioration of the building. In 1814 the College petitioned for, and succeeded in obtaining from Parliament, an Act to allow it to hold its meetings and exercise its powers within the City of Westminster. But the really effective influence in bringing about the removal was that of Sir Henry Hallford, who was elected President at the early age of 54 in 1820 and remained in the chair for the univalled term of twenty-four years—in fact until his death in 1844. He was physician in ordinary to four sovereigns, and through his personal influence with George IV and the Prime Minister, the Earl of Liverpool, was largely responsible for the grant on the present site of the College in Pall Mall East, then valued at £6,000, for ninety-nine and a half years, this was extended in 1864, during the presidency of Sir Thomas Watson, by an Act of Parliament to nine hundred and ninety-nine years. The architect of the present house, Sir Robert Smirke, R.A., also designed the British Museum, the General Post Office in St Martin's le Grand, and numerous other well known buildings. In 1822, while the new College—which with its fittings cost £25,000—was being erected, George IV showed his appreciation of the character and abilities of Sir Henry Hallford by declining that every future President of the College should for the time being hold the office of physician in ordinary to the King. But this high honour to the College apparently lapsed, for the next President (1844-56), Dr John Aitken Paris, did not receive any Court appointment to Queen Victoria. At 3 p.m. on June 25th, 1825, there was a grand ceremonial opening of the new College, attended by no fewer than five dukes of the blood royal and many other distinguished personages, Sir Henry Hallford, wearing the decoration of the Royal Guelphic Order (K.C.H.) conferred on him that morning, delivered an eloquent inaugural oration in Latin to the three hundred auditors, who were subsequently entertained at a sumptuous collation until about 5 p.m., when the President and some fifty of the ninety-one Fellows solemnly retired to the library to hold the Comitia Majora. The centenary of this opening was celebrated at the College on the night of June 25th, 1925, by a *conversazione*, arranged by the Treasurer, Dr S. Phillips, and attended by some four hundred of the Fellows, Members, and guests, including ladies and some of Sir Henry Hallford's descendants.

¹ *General Systematic Bacteriology*. By R. E. Buchanan. Ph.D. Monographs on Systematic Bacteriology. Baltimore: Williams and Wilkins Co. London: Baillière Tindall and Co. 1925. (Roy. Bro. pp. 597)

The guests were received in the library by Sir Humphry and Lady Rolleston. It is a fine room, and in it are hung some of the most precious of the College portraits—those of William Harvey (by Janssen), Radcliffe (Godfrey Kneller), and Sir Thomas Watson, prints were on view in two rooms, and by the generosity of Lord Ashfield of Southwell three cinematograph shows of nature films were given in the lecture room. The censor's room, the handsome panelling of which dates from 1674, when the house in Warwick Lane was built, contains the fine portraits of Richard Warren (Grimsborough), Linacre, Thomas Sydenham, Sir Samuel Guth, William Heberden the elder, of the *Commentaries*, whom Samuel Johnson called "Ultimus Romanorum, the last of the learned Physicians," Sir George Baker, and of other well known physicians. Altogether the College possesses one hundred and twelve portraits in oils and six thousand engravings of physicians, they have recently been catalogued by the Huxleyan Laboratory, Dr Arnold Clapham—a labour of love, but nevertheless a very onerous task. The walls of the reading room on the ground floor also carry a number of fine portraits, especially the full-length presentments of Sir Henry Hallford (Thomas Lawrence), Sir William Jenner, and Sir Richard Quain. The library, of about forty thousand volumes is particularly rich in old books, more than four thousand dating from before 1600, of these about one hundred were rescued from the College when burnt down in the Great Fire of London. Much interesting information of a personal and even gossip character is given in *The Gold-headed Cane*, written by Dr William Macmillan and published anonymously in 1827. A second edition appeared in the following year. It was supposed to be the reminiscences of the cane carried successively by Radcliffe, Mead, Astle, Pitcairn, and Matthew Baillie. In 1884 Dr William Munk published a much expanded edition carrying the story down to 1858. All these editions are now rather difficult to pick up. In 1915 there appeared from the publishing house of P. B. Hoeber (New York) a fourth edition, with an introduction by Sir William Osler and a preface by Dr Francis R. Packard, the editor of the *Annals of Medical History*, thus, like the fifth edition in 1923, with an introduction and annotations by Dr G. C. Percher, reproduced the text of Macmillan's second. The gold-headed cane, one of the curiosities of the College, reposes, with Harvey's dissecting pointer and other interesting relics, in a case in the large library. The exterior of the College has now, to match the adjoining Canada House opened by the King and Queen on Monday, put on creamy white in place of the sombre hue that has characterized it for many a long year.

WOMEN'S WAR MEMORIAL

THE FIVE SISTERS WINDOW in York Minster is one of the most famous in Christendom, there is nothing quite like it anywhere else—nothing, at any rate, on the grand scale. The architect must have been a bold man. The window of five lancet lights occupies practically the whole of the end of the lofty north transept, soaring without tracery in austere simplicity to the roof, the middle light is the highest, the others dropping with the curve of the rich York is not rich in stained glass, and the visitor is constantly drawn back to the crossing of the nave from which the great window is best seen. It is in grisaille—that is, the general effect is a pattern in grey with a few spots of colour. It looks like transparent tapestry, and the story is that five sisters in the thirteenth century embroidered the design. The window had got into rather bad condition, and had been glazed outside, thus the amount of light passing through was diminished. The menace of German bombs

caused it to be taken down, it was then seen that both the glass and the lead mouldings were in bad condition. At this stage the idea occurred to Mrs. Little, a lady residing in York, of inducing women to collect money enough to put it in order as a memorial to women who gave their lives in the war. The appeal was immediately successful, the £3,000 required was received within nine weeks, and enough came in afterwards to pay the cost of an oak screen bearing a roll of honour containing the names. It has been placed in the St. Nicholas Chapel near the window, and has twelve panels bearing altogether 1,400 names. One panel contains the names of the medical women—Laura Foster, Elsie Impey, Sybil Lewis, Isobel Tate, Marion Wilson, Elsie Inglis, and Louisa Woodcock. Each panel is covered by a door, and that to the medical women bears the emblem of the medical profession—the rough stick with the twisted serpent—made from a drawing of the emblem designed for the Gates of Honour the British Medical Association has just put up at the new house. The owner of Rievaulx Abbey, in northern Yorkshire, gave the lead for the restoration, it, therefore, is also of the thirteenth century. All the work was done in the Minster workshops, and the reinstated window was unveiled by the Duchess of York on June 24th. Deputations from all branches of women's war services were present in uniform, and the medical members in academic dress. A procession was formed, which passed through the streets, lined by civilians and thousands of spectators, to the Minster, where a short religious service was held. Representatives were present from the Dominions also from the Home Office, the India Office, the Air Ministry, the Royal Navy, the Army Council, the mercantile marine, Queen Alexandra's Royal Naval Nursing Service, Queen Alexandra's Imperial Military Nursing Service, the Territorial Force Nursing Service, Princess Mary's Royal Air Force Nursing Service, Joint Committee of the British Red Cross and Order of St. John of Jerusalem, Queen Mary's Army Auxiliary Corps, Women's Royal Naval Service, Women's Royal Air Force, Women's Foreign Corps, Women's Land Army, Scottish Women's Hospitals, Friends' War Victims Relief Committee, and Serbian Relief Fund. Miss Frances Evans, M.S., M.B. Lond., who had charge of the French hospital at Abbeville Royumont during the war, represented the Medical Women's Federation. At the same time as the ceremonial was taking place in York, commemoration services were being held in South Africa, South and West Australia, Tasmania, New Zealand, and Canada. The knowledge that these services were taking place made the words of the Archbishop in his address particularly true—"The emotion which unites us here is, as it were, a beating of the Empire's heart."

THE CIVIL RESEARCH COMMITTEE

A STATEMENT was made about the functions of the new Committee of Civil Research in a Treasury minute issued last week. It stated that the president of the Committee will be the Prime Minister and the regular chairman to act in his absence a Minister nominated by him. The members of the Committee will be such persons as are summoned by the Prime Minister or the chairman. It is modelled on the Committee of Imperial Defence, and, like it, will be an advisory body without administrative or executive functions. Its duty will be to give connected forethought from a central standpoint to the development of economic, scientific, and statistical research in relation to civil policy and administration, and it will define new directions in which inquiry would be valuable within these limits. The Committee will consider such questions as are referred to it by the Cabinet, the president, the chairman, and Government departments, and the president or chairman may summon for consideration of particular business

such outside economic, scientific, or statistical experts as he may think fit. It will be authorized to refer particular inquiries to special subcommittees, which may include outside specialists as well as expert officers of the department or department concerned. Departmental officers may be appointed to act as secretaries of such subcommittees. The scheme has been approved by the Treasury. The Earl of Balfour (Lord President of the Council), in reply to a question by Viscount Haldane in the House of Lords on Tuesday, said that the Committee was an additional wheel required to complete the mechanism of Cabinet government, but would not substantially modify that government. He specified three directions in which its assistance would be immediately available: it would deal with matters which concerned more than one department, with matters which, though they concerned only one department, were abnormal and raised problems of unrecustomed magnitude with which the fixed organization of the department was not well capable of dealing, and it would afford a convenient method by which the Dominions could be called into counsel at their desire if any question were raised in which they were specially interested. The defects of the existing machinery of government could not be cured by any other method. Royal Commissions conducted important investigations, but their functions were not conducive to rapid administrative action, especially because they had fixed references from which they could not depart, and lacked continuity. If the new Committee was to work well it must be with the full assent and co-operation of existing departments. The Committee would not be entitled to dictate in the smallest degree to any Minister or any Ministerial department, but it would serve to bring departments together to deal with problems no department was capable of dealing with alone.

ROYAL MEDICAL BENEVOLENT FUND

THE eighty-ninth annual report of the Royal Medical Benevolent Fund, for the year 1924, is a document we have studied with mingled feelings. On the one hand, we find a record of unselfish and devoted work on the part of a few of our colleagues. On the other hand, it is scarcely a credit to our profession that the income of a charity of this kind should be considerably less than £10,000. It is true that the Fund is rather better supported than it was forty years ago. Thus in 1884 there were 25,321 names on the *Medical Register*, and the income of the Fund was £3,068, in 1924 registered practitioners numbered 49,958, and the income was £9,189. Nevertheless, while the demands on the Fund increase steadily every year, the income grows very slowly, nearly half of it is derived from invested property, subscriptions and donations amounting only to £4,846. While the Committee of Management is able to record an increase of £1,000 in new subscriptions, old subscriptions fell off, from death and other causes, by the same sum. The amount expended in grants (numbering 343) was £5,001, and in annuities (numbering 147) £3,467, the working expenses were £1,254. All current subscriptions and donations are paid into the grant account, out of this the monthly grants are made with which our readers are familiar from the summaries of sad cases which appear from time to time in the columns of the *BRITISH MEDICAL JOURNAL*. Not only do the applications for help become more numerous each year, but the increase in the cost of living makes it necessary to give larger grants than formerly whenever possible. The amount of hardship and even starvation of which many of the older applicants complain is so distressing "that if it could only be made better known to the profession, there would at once be a large wave of benevolence, which would pour money into the funds of the society." Among the ways in which

further support has been sought of late years is the sending out of a letter written by a vice-president or a local secretary and reproduced in facsimile, another is the posting of reminders to those whose subscriptions have lapsed for some time. Acknowledgement is made in the report of the great assistance rendered to the Fund by the British Medical Association in the collection of subscriptions. During 1924 the Association forwarded £1,110, being an increase of £200 on the amount collected in the previous year. A gift of £210 from the Medical Insurance Agency is gratefully acknowledged, and in this connection the Committee of Management places on record its regret at the death of one of its members—Dr G. E. Huship, late Treasurer of the British Medical Association, who was instrumental in obtaining liberal grants to the Fund from the Agency, of which he was chairman for fifteen years. The report includes some account of the work of the Guild, or Ladies' branch of the Fund, which renders invaluable help, it has district representatives who get into personal contact with the grantees, and are able to advise about gifts of comforts in the shape of special foods, clothes, and coals. In a great number of cases, especially where there are children to be educated, the two funds work together, and constant and close co-operation is maintained between them. We commend the Fund and the Guild to the sympathetic notice of all our readers.

THE CONSERVATIVE TREATMENT OF ECLAMPSIA

THOUGH there is still some disagreement about the details of the treatment of eclampsia, it appears to be generally agreed that conservative measures are superior to such radical procedures as delivery by high forceps, forcible dilatation of the cervix, and vaginal Caesarian section. Last July Professor Stroganoff of Leningrad presented a paper to the Royal Society of Medicine which included an account of the special chloral treatment associated with his name, it was reported in our issue of July 12th, 1924 (p. 53). Three articles on this subject have now been published in the *American Journal of Obstetrics and Gynecology* for March, 1925. Dr H. J. Stander, who has studied the Stroganoff method in Leningrad, discusses this treatment in detail, and points out two steps in the method which appear to him irrational. He believes that chloroform used in the small quantity stipulated by Stroganoff cannot produce a satisfactory narcosis, and the possibility of chloroform poisoning is a further argument against its use. Dr Stander does not agree with Professor Stroganoff that intubation of 200 to 300 c.c. (7 to 11 fl. oz.) will be of any material value in the lowering of the blood pressure or in eliminating toxins, and holds that it should not be employed at all, or alternatively that larger quantities of blood should be withdrawn up to as much as 1,000 c.c. (35 fl. oz.). Dr E. Speidel compares the Stroganoff method with the treatment advocated at the Rotunda Hospital in Dublin, the McPherson system, and the use of veratrum viride. He suggests that the value of veratrum treatment may have been discounted unduly because too small a dose has been given, and states that Dr Gillespie advises that in antepartum eclampsia 60 minims of veratrine—a standardized preparation of veratrum—should be injected hypodermically as the initial dose, and followed by doses of 15 minims every ten minutes, until there is sighing respiration, copious bilious vomiting, and a soft pulse with a rate of 40 to 60. No other advocate of this remedy appears to have recommended such heroic doses. The treatment recommended by Dr Ross McPherson resembles both the Rotunda and Stroganoff methods to some extent, but he depends entirely upon morphine for the narcosis. Dr Speidel, after trying this method for two years, was disappointed with the

results, the maternal mortality being high and the morphine tending to check elimination by the bowels and to produce pulmonary complications, in spite of the simultaneous administration of atropine. He found, moreover, that the morphine was insufficient as a narcotic, and that manipulations incited convulsions. Dr. Speidel, therefore, favours the Rotunda method, and suggests that reports by the larger maternity hospitals on the systems they employ should be collected annually in order to reach some definite conclusion with regard to the treatment of eclampsia. He considers that every hospital ought to establish a definite routine of treatment so that no time may be lost in dealing with any case. His other recommendations include the following: The eclamptic patient should be treated in a well lit room (not a darkened room, as recommended by Professor Stroganoff), she should lie on her side, with her head low and near the edge of the bed, particular care being taken to prevent the aspiration of secretion into the lungs. No anaesthetics should be used during the convulsions, but the administration of oxygen and nitrous oxide is advised as a preventive measure during manipulations. A hot wet pack, together with the uniform and continuous warmth obtainable by the use of an electrically heated blanket, will secure relaxation and hasten delivery. Venesection to the extent of 500 ccm (nearly one pint) followed by the introduction of 500 ccm of 10 per cent glucose solution, should be employed if the blood pressure is above 150 mm Hg and convulsions continue. Dr. C. L. King recommends the use of morphine, 1/2 grain being given to the patient on admission. Venesection to the extent of 500 to 800 ccm follows, the blood pressure being carefully watched and the procedure discontinued immediately it falls to 130 mm. If only a small amount of blood has been withdrawn and the convulsions have not been checked, this procedure is repeated. Dr. King reports that, as a rule, convulsions cease after this treatment, but if they do not 1/4 grain of morphine is given. He has employed 1 grain or more without harmful effects, and sometimes he uses in addition chloral hydrate and potassium bromide. The stomach and the colon are washed out subsequently. Under this treatment he reports that there has been no maternal mortality. Should labour begin during the treatment it is permitted to continue naturally, if it does not begin he thinks it should be induced, but generally not until convulsions have ceased and the patient's condition has improved.

THE HEATING OF LIVING ROOMS

THE Fuel Research Board of the Department of Scientific and Industrial Research has just issued a "technical paper" on the heating of rooms, and we have fortunately been able to induce Dr. Fraser Harris to study it for us. It is, he writes, a very good example of the investigation of a familiar, everyday problem by the combined methods of physics, mathematics, and physiology. The object of the research was to ascertain and express in scientific terms the conditions making for comfort indoors when the sources of heat were respectively coal, coke, gas, and electricity. Even "comfort" is a relative term, here it means comfort to one whose occupation is sedentary for several hours together. The observations were carried out in the Westminster Technical Institute. The paper opens with a succinct account of the physiology of the production and the loss of animal heat, and calorimetry generally. The equipment of the experimental room is fully described, as well as are the methods for measuring such variables as

air temperatures, wall and floor temperatures, velocities of draughts, and the total volume of air passing through the room in a unit of time. Radiation from the source of heat was measured in absolute units by a Richmond radiometer and by a Bone-Callander-Lates volometer. British thermal units were used. The distinction is clearly drawn between heating by radiation and heating by convection (heating of air), a subject about which there is a great deal of popular confusion. The experimental room received no direct sunlight, and therefore no heat of solar origin. All factors were investigated: the sizes of the rooms (1,000, 2,000, and 4,000 cubic feet), the number of persons (from one to six), the distances from the source of heat at which the occupants experienced comfort or the reverse ("zones of comfort"), and the relative humidity. Some interesting figures are given in comparing the proportion of heat received by the room with the total potential heat of the fuel or source. This ratio is called the "efficiency", thus, with the open coal fire from 17.5 to 25 per cent of the total heat-energy reaches the room as radiated heat, and 5 per cent more is received in convected air, making a total of from 22.5 to 30 per cent "efficiency", the rest (from 77.5 to 70 per cent) is lost up the chimney. The total efficiency of a modern gas fire is about 55 to 60 per cent—45 to 50 per cent by radiation and 10 per cent by convection. The total efficiency of an electric heater is 100 per cent, 70 per cent of this is radiated and 30 per cent convected. The efficiency of a "radiator" system (hot-water coils) is about 50 per cent. The various factors involved in the problem are stated so admirably that we may quote the paragraph: "The rate at which heat must be delivered to a room in order that its temperature may be maintained at a constant level depends upon the size, construction, and position of the room and upon the external weather conditions. When the heat is first turned on to a room in cold weather there is a gradual rise in the temperature of the air and fabric of the room, the total heat capacity usually being so great that a steady state is not attained for some days. When a steady state is reached, and there is no further rise in temperature of the structure, the amount of heat delivered to the room must be exactly balanced by the amount flowing out by conduction through the walls, floor, ceiling, windows, etc., together with that carried away by the air which passes through the room." The paper contains thirteen tables of statistics and six diagrams (curves). Table XIII is one of the most interesting: it shows the cost in pence for a sixteen hour day to heat by radiation rooms of the three different sizes, and with from one to six occupants, by means of the open coal fire, the open low-temperature coke fire, the open gas fire, and the electric heater. In commenting on this table it is remarked that "for continuous heating by far the cheapest means of providing radiation is an open fire of low-temperature coke, open coal fires are slightly more expensive, gas fires are about 2½ times as dear as coal, and electric heaters are 5½ times as dear as coal." The whole investigation, although carried out on lines of such scientific accuracy, is exceedingly practical, as one of the concluding sentences testifies: "Whatever the method of heating adopted, the cost will be closely allied with the completeness of the insulation of the rooms, and it is of the greatest importance to construct houses in such a way as to avoid high conduction losses." Builders, we fear, give very little heed to this principle in the construction of walls. An air space between two thicknesses of brick and double windows are two practical suggestions made. The pronouncement on hot-water radiators is valuable: "It will be seen that at 50 per cent efficiency hot-water radiators prove to be the cheapest method of heating continuously a 1,000 cubic foot room, but that for a 4,000 cubic foot room an open low-temperature coke or coal fire is cheapest

¹ Department of Scientific and Industrial Research. Fuel Research Board. Technical paper No. 12. The Heating of Rooms: a Comparison of the Costs of Different Methods on the Basis of Warmth Comfort. By Margaret Fishenden, D.Sc., assisted by R. E. Willgren, B.Sc. London: H.M. Stationery Office. Price 1s. net.

until there are more than three people in the room, when hot-water radiators again become the most economical." In an investigation of so exhaustive a character we would have expected some reference to the method of heating by hot-water piping the walls and ceilings of large buildings known as the "panel system," examples of which are to be found in Bush House, Kingsway, and in Austria House in the Strand. Similarly, the method adopted in Liverpool Cathedral, which is practically a return to the Roman method of heating the floors by means of hot air, might also have been alluded to, particularly since this method attracted so much attention in the press in the autumn of 1924. The data are all given in British units and the decimal system is not used, which will make comparison of the statistics with those of Continental works somewhat troublesome. There is a full bibliography and an excellent index, which occupies no less than four pages out of a total of forty-eight pages for the entire monograph.

AN INTERNATIONAL HEALTH CONGRESS

As travelling facilities increase the world grows smaller and more convenient for congresses and conferences, that is being discovered by all classes of the community, and questions which were at one time no more than national have become international, whether the objects are health, politics, religion, labour, or revolution. At the same time, owing to the great war, an enormous share of such wealth as has not been destroyed has been transferred from the Old world to the New, and the idealism which finds so congenial a field in America has opportunity for expressing itself in ways which make for the welfare of mankind. A recent example is to be found in the action of the United Fruit Company, whose headquarters appear to be at Boston, Massachusetts, though its activities must be mainly elsewhere. In 1923 it held a round table conference of nine medical superintendents of its hospitals in Central America. It is claimed, indeed, that the company has transformed great tracts of jungle into fertile and wholesome garden lands, has carried civilization into the tropics, and has been a pioneer in looking after the health and welfare of many thousand employees. The conference of 1923 decided that there should be a larger gathering, and invitations were issued to eminent workers in tropical medicine in the four quarters of the globe to meet at Kingston, Jamaica, on July 22nd, 1924, after the conference finished its work (on August 1st) the members were given opportunity to inspect the health activities of the company in Honduras, Panama, and elsewhere. The proceedings of the gathering at Kingston have been issued in a large and handsome volume,¹ with a preface by Professor M. I. Rosenau of the Harvard Medical School. The contributors from this country included Sir Arbuthnot Lane, Sir Leonard Rogers, Sir James Fowler, Sir Arthur Newsholme, Sir Thomas Oliver, Dr Arthur E. Horn, Professor John W. Stephens, and Dr John G. Thomson. Dr Bunting was present from Toronto, and many other well known authorities. Some seventy papers were read, mostly on subjects of great importance. We do not propose to attempt to give any account of the contents of the thousand pages of *Proceedings*, the striking fact is that such a meeting was held. The United Fruit Company is to be congratulated on the way in which it organized the conference. The volume of *Proceedings*, well printed and well illustrated, is defective in that while it has a table of contents there is no index, so that it will be very difficult to use it for reference on particular points as to which it ought to be available for ready consultation. Otherwise there can be nothing but praise for the enterprise and its outcome.

THE SECRETARYSHIP OF THE ROYAL SOCIETY OF MEDICINE.

THE Royal Society of Medicine has decided to mark Sir John MacAlister's retirement from the office of secretary, which took effect on July 1st, by appealing for funds to raise a memorial to his great work for the society. What this work has been has already been summarized in our columns. It is anticipated that his numerous friends will gladly contribute, and that Fellows of the society will be anxious to see a permanent memorial of the man to whom the existence of their institution is chiefly due. It is hoped that the memorial will take the form of some portrait in oil or stone. At its last meeting the council selected, from a very large number of applicants, Mr. Geoffrey R. Edwards, B.A. Cantab., to succeed Sir John MacAlister as secretary. Mr. Edwards was educated at St. Paul's School and St. John's College, Cambridge. He studied in Germany to qualify for the Woods and Forests Department of the Indian Civil Service. On his return from India he joined the Royal Air Force as a pilot. While up on active service he was wounded and had to fight in the enemy's country, and was imprisoned in Germany for fourteen months. Subsequently he served on the Repatriation Commission in Germany and on the Inter Allied Aeronautical Commission of Control. On demobilization he was appointed assistant secretary to the National Physical Laboratory, Teddington, where he has had considerable experience in library and editorial work and in organization. He takes up his duties on September 1st.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

In order to obtain designs for the permanent quarters of the London School of Hygiene and Tropical Medicine to be erected on the site adjoining Keppel Street, Gower Street, and Malet Street, near the British Museum, the board of management of the school in December last instituted a competition limited to five architects who had specialized in the planning and equipment of the type of building required, and appointed Sir Frank Brines, Director of Works at H.M. Office of Works, as assessor. The board, under the chairmanship of the Right Hon. Sir Alfred Mond, M.P., has now unanimously adopted the assessor's award in favour of the design submitted by Mr. P. Morley Holder, and he will be appointed architect for the new building. It will be remembered that the funds for the erection of the new building are being provided by the Trustees of the Rockefeller Foundation, who offered the British Government nearly half a million sterling for site, building, and equipment.

We greatly regret to announce the death, on June 27th, as the result of a motor-car accident, of Mr. Hamilton Drummond, F.R.C.S. Ed., assistant surgeon to the Royal Victoria Infirmary, Newcastle-on-Tyne, and a son of Sir David Drummond, formerly President of the British Medical Association. We hope to publish a memoir in an early issue.

THE Committee of the Royal College of Physicians of London and the Royal College of Surgeons of England is about to appoint a Stierfeld Research Scholar. The emolument will probably be £250 per annum and the tenure three years, at the discretion of the Committee. Applications stating the nature of the proposed research should be sent to the Registrar, Royal College of Physicians of London, Pall Mall East, S.W. 1, not later than October 1st. Further particulars will be found in our advertisement columns.

NINETY-THIRD ANNUAL MEETING of the British Medical Association, BATH, 1925

Doorway of St John's Hospital (From a wood engraving by Horace Gerrard)

THE ninety-third Annual Meeting of the British Medical Association will be held at Bath at the close of this month, under the presidency of Dr F G Thomson, physician to the Royal United Hospital, Bath, and consulting physician to the Royal Mineral Water Hospital. The Annual Representative Meeting will open in the Concert Hall of the Pump Room at Bath on Friday, July 17th. The statutory Annual General Meeting will be held on the afternoon of Tuesday, July 21st, in the Concert Hall, and on the evening of the same day the new President will deliver his Address to the Association in the Palace Theatre. The twelve Sections among which the scientific and clinical work of the meeting is being divided this year, will meet on the three following days, July 22nd, 23rd, and 24th. The list of Sections and sectional officers, together with the full provisional programme and time table and announcements about hotel accommodation, etc., are published in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL this week. On the last day of the meeting, Saturday, July 25th, there will be excursions to places of interest in the neighbouring West Country. We publish

below the fourth of a series of descriptive and historical articles on Bath. The British Medical Association last met in that city in 1878.

BATH AND THE POETS.

BY

JOHN HATTON,

DIRECTOR OF THE ROYAL MINERAL BATHS

BATH certainly has done its share in inspiring the poetic muse. Whether it is the effect of its waters, or the stately grace of its architecture, or the beauty of its situation, or whether it is that literary interests are here rather more strongly developed than is usual and the stirring of wit on it produces almost a shower of divine sparks, might form a pretty subject for debate. Whatever the cause, this much is certain, poets do write about it. About Bath itself, its springs, its buildings, its beauties, natural and artificial. And the men and women of Bath who live only through their creators' pens, but more vividly to many than those of flesh and blood—what a fascinating and very human company they form. Across the pages of the last five hundred years or more they make a goodly procession, these literary characters of Bath. Chaucer is responsible for their leader

A good wife was there of beside Bath
But she was some deal dwe, and that was seith
Of cloth making she had such an hant
She passed them of Ypres and of Gaunt

Next comes Shakespeare

Cupid lud by his brand and fell asleep
A maid of Druis thus advent'ge found
And his love finding fire did quickly steep
In a cold valler fountain of that ground
Which borrow'd from his holy fire of love
A dateless lively heat still to endure
And give a seething bath which yet me prove
Against strange maladies a sovereign cure

It is not only the poets who have been inspired by Bath, the novelists and the dramatists demand a place in the procession. Here, headed by the Strip-violeted Rodenel Pandom, is the queer collection gathered together by Dr Tobias Smollett in the intervals of failing to build up a plot and quarrelling with his professional brethren.

Once everybody knew them, now they are but almost forgotten names, and so they pass disconsolate—Miss Snapper and Miss Snapper, and Narcissa. Mr Freeman and Godfrey Gruntlett. A faint "Hallo!" comes from the fox-hunting Squire, and Peregrine Pickle can still find a few nodding acquaintances. Then, strangely incongruous in such surroundings, and like a faint ghost, for he does not really belong here and is only allowed in our procession because his

spirit was evoked in Bath, comes Robinson Crusoe, for here it is said Defoe met Alexander Selkirk and heard from his lips the story which later he gave to the world as the history of Robinson Crusoe.

Tom Jones and Squire Allworthy are far from shadowy, for both have good Somerset blood in their veins, even if the real Squire Allworthy—for he is almost a portrait—was that great Cornishman, Ralph Allen, who became the Man of Bath. Fielding is naturally well represented, for he lived on the edges of Bath, in Twerton and Widcombe, and was a welcome guest at Prior Park, and so Squire Western comes blustering along, and Tom nearly loses Sophia, and Miss Bridget Allworthy and the Blifils complete a group typical of the West Country when George the Second reigned.

There was a breath of the fresh air of the downs in Fielding's men, and something of the West Country apple blossom in his women, but the artificiality of the town is thick on Christopher Anstey's sprightly, amusing, objectionable B---n---r---d Family. Mr Simpkin B---n---r---d, Miss Prudence B---n---r---d, Miss Jennet W---d---n and Tabitha Ruit, in spite of their long journey, find Bath to their liking.

Two hundred and sixty long miles are we come
Tis a plaguy long way—but I ne'er can repine,
As my stomach is weak, and my spirits decline,
For the people say here—be whatever your ease,
You are sure to get well if you come to this place

for after recovering from their journey and the "Charming sweet sounds both of fiddles and bells," which welcomed their arrival, they soon find that

Of all the gay places the world can afford,
By gentle and simple for pastime adored
Fine balls, and fine concerts, fine buildings, and springs,
Fine walks and fine views and a thousand fine things,
(Not to mention the sweet situation and air)
What place my dear mother with Bath can compare?

There seems no keeping *The New Bath Guide* out of anything about Bath, and even if we nowadays can scarcely agree with Horace Walpole that "so much humour, fun and poetry, so much originality, never met together before," this witty, slightly indecent book probably gives the truest

picture we have of, at any rate, a large section of Bath society in the eighteenth century.

Now comes a familiar group, benighted and feathered, powdered and perfumed. Sir Anthony Absolute drinking protestingly his glass of water and bullying his son between each dose, Sir Lucius O'Tigger telling Bob Acres of the very snug lying in the Abbey, Lydia, languishing exquisitely, and Julia distracted by her Fankland, Mr Fag (of Bath), David (of the county), and the useful Lucy, and Miss Malaprop herself, destined to bring Mr Sheridan a more lasting fame than all his eloquence and statesmanship.

Fanny Burney has passed quickly with all the people from *Evelina*, and then there is another faint whiff of bygone perfume—lavender, surely, this time, clean and with just a tinge of pungency—and Catherine Morland appears, with Henry Tilney, and the General. Bath gave Jane Austen many of her characters, and with her one may still sit in the Pump Room and see the perennial comedy played again and again—the same play, but brought up to date and redressed, as the producers say. Miss Thorpe and Isabella and John Thorpe are there, and Miss and Mr Allen, and James Morland and Miss Tilney are not far to seek.

Next we hear the voice of Cyrus Angelo Bantam, Esquire, Master of the Ceremonies.

"Welcome to Bath sir. This is indeed an acquisition. Most welcome to Bath sir. It is long, very long Mr Pickwick, since you drank the waters. It appears an age, Mr Pickwick. Remarkable!"

This leads in Mr Pickwick himself, the devoted Sam Weller, and those sticklers for the rigour of the game, the Dowager Lady Snaphrugh and Miss Colonel Wugsby. (Miss Bolo has already gone home in a flood of tears and a sedan chair) and Mr Winkle, still suffering some embarrassment from his endeavours to be helpful, and a little group of footmen and fat chairmen and thin chairmen who hurry up to take their places in the procession, wiping from their lips the remains of boiled mutton with the usual trimmings.

More and more figures pass. There is Monsieur Beaucaire and the Incomparable Bellairs, but many are shadowy and have fading names. Victorians and Edwardians and an ever-growing group, the creatures of this present age. So we leave them, with Mr H G Wells's Sir Richmond Hardy and Miss Grammont.

"They went to the parapet above the river and stood there, leaning over it elbow to elbow and smoking cigarettes. Away in some sunken gardens ahead of them a band was playing and a cluster of little lights about the bandstand showed a crowd of people down below dancing on the grass. These little lights, these bobbing black heads and the lilting music this little inflamed centre of throbbing sounds and ruddy illumination made the dome of the moonlit world about it seem very vast and cool and silent. Our visitors began to realize that Bath could be very beautiful—there was Pulteney Bridge with its noble arch its effect of height over the swelling river and the cluster of houses above more beautiful than the Ponte Vecchio at Florence. It is the most beautiful bridge in the world," said Miss Grammont.

The members of the British Medical Association may perhaps have some means of rendering themselves immune to the attacks of *B. pocticus*, *B. bathoniensis*, or the close of the Annual Meeting may see a serious outbreak of such Friewell Odes as Lady Mary Wortley Montagu's beginning "To all you ladies now at Bath." And if a few moments have been snatched from Sectional Meetings and other important matters, to view Bath from Beechen

Chiff and see the grey city in its green cup, someone may say with the eighteenth century John Scott

Bath ere I quit thy pleasing scene
Thy beechen cliff I'll climb again
To view thy mountains' vivid green,
To view the hill surrounded plain
To see distinct beneath the eve
As in a pictured prospect nigh
Those attic structures shining white
That form the sunny crescent's bend

Or it may be after nightfall, when the velvet valley is pink with a thousand points of light, and the city is, as Henry Chappell, the porter poet of Bath, says

Bathed in ghostly light
Asleep at peace beneath the witching beam,
Seeming within the soft embrace of Night
To be the beautiful City of a dream

A great poet can praise greatly, and few finer tributes have been paid to any city than Swinburne's *Ballad of Bath*—too long to quote in full here, and too beautiful to quote in clipped extract.

Many writers have found Bath a congenial place of residence. Frederic Harrison spent the last years of his long life here, Mrs C N Williamson, who has ranged over most of the countries of Europe "Rita," who found in Bath both the characters and setting for one of her most popular works, and that distinguished authority on literature and wines, Professor George Santsbury.

Bath has a famous writer this year is Mayress, Madame Sarah Grand, who will assist in welcoming the members of the Association to the city she loves and has made her home.

"I happened upon Bath accidentally" (Madame Sarah Grand has written). "One day the question was, 'Where shall we go for a change?' And one said 'Let's go to Bath the Beautiful.' So we went for a month and at the end of the month we were singing a chorus song of praise like the Lotus Eaters and one said, 'Let's stay for ever in Bath the Beloved.'"

So we stayed, where history, archaeology, and the picturesque jostle each other at every turn where poetry and romance are in the air, and character walks the streets where music holds its own and philanthropy has more than enough to do where the invalid throws away his sticks or forsakes his bathchair in a week, where the provision shops overflow with good things for the gourmet and he may have green peas and new potatoes out of his garden till the end of November. And as to society—surely there never was a more sociable, more hospitable, friendlier place or pleasanter people, or more liberal minded. It is not so Bath and die, but see Bath and live, and let live. Differences of opinion all go into the social stockpot here and reappear as food for conversation. Bitterness dies in Bath of the prevalent sense of humour and love of fun.

SICKNESS INSURANCE FOR MEDICAL MEN

The risk every medical man runs to a greater or less extent of being stopped in his work by disablement through illness or accident is now realized by most members of the profession. The work of the majority is so personal in its nature that if a man is prevented from attending to it himself he must suffer serious pecuniary loss, both direct and indirect. Physicians, surgeons, and specialists have to depend entirely upon their ability to give constant personal attention to their patients, and the same is true of general practitioners, though perhaps to a lessened extent when they are in partnership. Those who are engaged in the public health service, or who hold institutional appointments, are not exposed to quite the same immediate risks, as frequently the contract of service

The Royal Roman Bath and Cross Bath with Royal United Hospital in the background (From a wood engraving by Horace Gerrard)

they hold with a local authority is adequate to help them through a temporary period of illness or disablement, but if the period becomes prolonged they also are exposed to serious losses. It is therefore incumbent on every medical man engaged in practice to build up for himself a strong reserve fund which can be drawn upon to meet the expenses incurred through disability from accident or illness. Probably the surest and safest way of providing for such contingencies is by an insurance contract. Recent experience has shown, what indeed ought to have been obvious, that the terms of the contract must be very carefully examined and that it should not be concluded without obtaining skilled advice.

An interesting example of how men have helped themselves is provided in the development of what is known as the Holloway group of friendly societies. Members of friendly societies enjoy certain privileges, but have to submit to certain restrictions, which tend to impair a society's usefulness to members of the medical profession. There have also been tried during the last fifty years various methods of protection by insurance companies who have sought to meet the requirements of the medical and other professions. The forms of protection offered by the insurance companies have followed two main lines.

1. An annual contract—that is, a policy providing for a fixed payment in the event of disablement from sickness or accident during a period usually not exceeding twenty-six weeks, together with capital sums payable in the event of death or loss of limbs or eyes. As a rule these contracts can be obtained without any medical examination, and it is possible for either party to terminate the contract at the end of the policy year. These contracts are obtainable at a comparatively low premium but they are of less value to the medical man who desires protection over a long period than to commercial classes with less need for sickness insurance.

2. The non-cancellable contract—that is to say, a policy which providing its conditions are complied with can be continued in force until an agreed age, but not beyond age 65.

The companies granting these contracts have no power to vary the conditions of the policy or exclude any diseases no matter how frequent or prolonged the disablements may be. The permanency of these contracts gives them an increasing value, and they have been very largely taken up by all sections of the medical profession. The policies for which there is the largest demand provide for payment in the event of disablement in one of two well established ways.

The first is by a contract for immediate payment for any disability which lasts more than seven days the payment continues in full for twenty-six weeks but is then reduced by one-half for the remainder of the disablement up to the termination of the agreed period.

The other is the deferred non-reducible system. Under it there is no payment for the first four weeks, three months, or six months of any disablement, as may be preferred, but the full amount is paid thereafter so long as the disablement lasts up to the agreed age.

Quite recently a new form of policy has been granted, which provides for immediate and non-reducible payments. Whilst attractive this form of contract is unsound in theory. In the first place the statistics upon which the premiums have been calculated do not extend to show a non-reducible benefit, and the companies offering this form of contract are therefore experimenting with this class of insurance. In the second place, such a contract removes the principal inducement to an early recovery from disability, which is undesirable both from the point of view of the company and the assured.

Yet another experiment is being made which has appealed particularly to some members of the medical profession, and should receive careful consideration. It is a practice of the friendly societies to make payment to its members who are totally unable to follow the occupation in which they have been engaged. Some insurance companies have granted contracts of a similar nature to surgeons and general practitioners. It would appear that if it is

possible for a friendly society to grant this form of protection then there ought to be no reason why an insurance company should not do it, but it must be borne in mind that while a friendly society has the privilege of altering its conditions by a vote of its members, there is no such freedom reserved by an insurance company. Once an insurance company has granted its contract it is bound by its conditions. It may sound very attractive to a surgeon to be able to get a sickness and accident policy which purports to issue a definite weekly payment if he is unable to follow the specific side of the profession that he is practising, but it must be recognized that the premiums that are charged for sickness and accident insurance are not calculated to provide for any such risk, and, while it may appear a very desirable contract, it may really be that the company is undertaking liabilities for which no adequate provision is being made. This point is of such importance that it needs to be carefully examined. For instance, supposing a surgeon seriously injured his right hand, it might prevent him from following his ordinary professional duties, and be sufficient to enable him to establish a claim within the meaning of the policy, but when the injury had healed, although he might still be unable to operate, the condition of his general health might not be in any way impaired, and he would be able to devote his knowledge and attention to another part of the profession. He might be unable to earn so large an income as when doing his special work, but he might be able to make good in another direction. An insurance company granting such a policy might have to pay an annuity up to the agreed age, although the policy holder was in a position to make an income in another branch of the profession, and was actually doing so. Some of the insurance companies that have had considerable experience in sickness and accident insurance decline to grant such contracts.

Another effect of this condition providing for total incapacity to follow a specific line of practice is to make possible claims for partial disablement. An experienced actuary has given the following opinion upon this aspect of the subject:

"The sickness portion of a permanent sickness and accident policy only covers total disablement. It is always possible for an additional premium to protect oneself against partial disablement by accident for a sum assured, which is usually one-fourth or at the most one-third of the sum assured payable in event of total disablement but it is not possible to effect an insurance against partial disablement by sickness. It would probably be regarded as rashness in this age of enterprise to predict that any particular condition would never lend itself to insurance treatment but if an exception to an otherwise wholesome rule, viz., not to prophesy before you know, could be made I should venture to claim that this exception must be that of providing partial disablement benefit under a sickness policy. It is a multifarious condition capable neither of precise statement nor of treatment from the insurance standpoint. The system can only be framed upon general lines and it can only provide therefore for total disablement."

The position with regard to sickness and accident insurance has now reached a stage which calls for the most serious consideration of the profession. The companies that have the longest experience have been operating for about forty years, but they will probably require carefully to observe their experience for another fifteen years in order to obtain trustworthy vital statistics. The selection of risks requires special skill, and the incidence of certain diseases demands constant observation. A conservative attitude towards this special class of insurance is therefore to the advantage of both the general public and the companies.

The oldest companies enjoy large reserve funds, which are periodically valued on a stringent actuarial basis. In life assurance it is always possible to know the basis of the valuation that the company uses, and the same public should be given to sickness and accident funds. There is one office that is always prepared to give this information upon application. In all cases a separate account for sickness and accident funds should be produced. It is hoped that the Board of Trade Committee which is considering the Assurance Companies Act, 1909, will make it compulsory upon all companies transacting permanent sickness business to make returns to the Board of Trade.

in the same manner as life companies do at the present time

It is desirable that a medical man, before entering into any contract for sickness and accident insurance, should avail himself of the guidance that is obtainable from the Medical Insurance Agency (British Medical Association House, Tavistock Square, London, W.C.1)

It cannot be too often emphasized that, just as a medical man who intends investing funds seeks either the counsel of his bank manager or stockbroker, from whom he expects an independent opinion, so he should seek in like manner the aid of the Medical Insurance Agency, which exists to give him free, independent, and impartial advice upon all insurance matters

INTERNATIONAL CONGRESS OF RADIOLOGY

FIRST DAY'S PROCEEDINGS

THE International Congress of Radiology began its heavy programme of work on July 1st at the Central Hall, Westminster, under the general presidency of Mr C THURSTON HOLLAND of Liverpool. The members attending, exceed by at least one hundred the anticipations of the organizers. Up to the eve of the Congress close upon 500 members had registered, more than half of whom came from abroad. In the first list of 350 arrivals, 60 were from Germany, 30 from France and Belgium, 12 from Italy, and just over 50 from the United States. Constantinople and Buenos Aires and Moscow were all represented, and a contingent came from the State Institute of Roentgenology, Leningrad.

On the evening before the Congress a reception, which was very largely attended, was given by the executive of the Congress at the house of the Royal Society of Medicine. Members and their friends were received by Mr Thurston Holland. An exhibition of old books, prints, and curiosities in the possession of the Royal Society of Medicine had been arranged, there was a cinematograph display, and Dr Murray Levick gave a lecture, illustrated by his own photographs, on the habits of the Adello penguins in the Antarctic.

OFFICIAL OPENING CEREMONY

H.R.H. the DUKE OF CONNAUGHT opened the Congress officially on Wednesday afternoon, July 1st. Among those on the platform, besides the President and officers of the Congress, were Mr Neville Chamberlain (Minister of Health), Lord Dawson of Penn, Sir Humphry Rolleston, and Sir George Newman. Delegates were introduced representing the radiological societies of the Dominions and of various foreign countries.

The Duke of Connaught said that it was an eloquent tribute to the value of Roentgen's discovery that, thirty years afterwards, such a large body of scientists and medical men should meet to discuss the many directions in which the science had developed. The dreams of the earlier days might not have been all fulfilled, but there were reasons for believing that with the more intelligent appreciation of the effects of x-rays more striking advances might be made. The consuming question that interested scientists and medical men the world over was the discovery of the cause and treatment of cancer. No surer method of promoting cordial international relations could be imagined than the meeting in congress of the leading intellects of all countries. His Royal Highness went on to speak of the value of mobile x-ray outfits which could be taken to the patient's bedside, of the work of the British Institute of Radiology, and of the research on radium which was proceeding in this and other countries.

Mr NEVILLE CHAMBERLAIN welcomed the members on behalf of the Government. He said that few could have anticipated in the early days of Roentgen's discovery what it meant for mankind. Such succeeding discoveries in this province seemed only to lift the curtain a little higher, and to indicate still further possibilities opening out. He did not believe that advances could be made except by continual research and experiment, to the interplay of

minds devoted to these problems. It was the duty of his department to do all that it could to encourage research. At present this was hampered, so far as radium was concerned, by the fact that radium was both scarce and dear. Mr Chamberlain went on to say that the path of exploration was always strewn with wreckage, and very often with the bones of explorers, and radiology had been no exception. Not a few of the pioneers had fallen victims to dangers which at the beginning were unrecognized. All honour to such pioneers! They had moved the rocks for others. He did not doubt that when the Congress closed all its members would feel that another step had been taken towards further triumphs for the benefit of humanity.

Sir HUMPHRY ROLLESTON conveyed the thanks of the Congress to His Royal Highness, and went on to speak of the British Institute of Radiology and the hopes and ambitions it represented. He could not help feeling that the Congress and the Institute were very closely related. The Congress was in the butterfly stage, and worked intensively for a short time, but the Institute was in the larval stage and carried on its work from day to day. The Institute deserved all possible encouragement and help, for it was a sort of central bureau where all matters connected with radiology could be stored, discussed, and provided to any radiologist or other medical man requiring them. The Institute would become the centre of a worldwide organization for systematic research.

INTERNATIONAL UNITS AND STANDARDS FOR X-RAY WORK

A joint meeting of the Sections of Physics and Radiology was held on Wednesday morning to discuss the subject of international units and standards for x-ray work.

Sir WILLIAM BRUCE, in a brief introduction, referred to the difficulties surrounding the problem, which he said, must be settled on the basis of compromise. There were three factors which must be isolated: (1) the determination of a scientific unit, which was a matter of physics pure and simple, (2) the determination of a standard or description of an apparatus which could be used for comparison, (3) the comparison of this standard with the results obtained in treatment. It was of no use arriving at any one of these factors to an extreme conclusion and leaving the others indefinite, because, just as the strongest part of a chain was its weakest link, so any indefiniteness in any one of these divisions would govern the value of the work in others.

Dr H. BLEIBERG, speaking in French, said that radiologists must look to radium to supply the physical unit of dosage for fundamental standardization. He called upon radiologists of all countries to attempt a standardization of dosage which might be common to them all, and to elect an international committee for the study of this very important question, such committee to be composed of medical men and physicists.

Dr N. S. FINZI (London) seconded this proposal. The most difficult question, in his view, would be the setting up of a biological unit on account of the numerous factors, such as wave lengths of radiation employed and duration, which had to be reckoned with. If radium were used in standardization, the beta radiation should be eliminated.

Others who joined in the discussion were Dr W. ALTSCHUL (Pirgny), Dr I. SER SOLOMONY (Paris), Dr J. H. SHAW (Cardiff), and Dr H. MOORE (London). The last-named expressed the opinion that the most important step was to provide radiologists with a generating apparatus with which they could get an x-ray beam of definite quality. Given this factor, the problem of dosage would solve itself. The solution was in the hands of radiologists if they chose to scrap their present apparatus and to install a constant voltage apparatus, the only deterrent was cost.

A motion to elect an international committee for the study of this question was carried.

Periodical International Congresses

The international delegates conferred during the meeting, and it was agreed that the Congress should be constituted the first International Congress of Radiology, which means that it is to be followed by others in different countries.

Victoria.

[FROM OUR SPECIAL CORRESPONDENT]

NEW HOUSE OF THE VICTORIAN BRANCH

THE Victorian Branch of the British Medical Association decided a short time ago to build itself a new house. It has recently been completed and was formally opened on May 20th. It is of concrete, in three stories, and has cost £11,000. In the entrance hall a memorial has been erected to members who fell in the great war, on the same floor is a meeting hall capable of seating 350 people. On the first floor is a library, a reading room, the council chamber, and offices.

At the opening ceremony the chair was taken by Dr Argyle, President of the Branch, who was accompanied on the platform by the Attorney-General of Victoria, the Lord Mayor of Melbourne, the two vice-presidents of the Branch, the vice-president of the New South Wales Branch, the Dean of the Faculty of Medicine, Melbourne University, the chairmen of committees, the honorary secretary, and the chairman of the Building Committee. Dr R. H. Fotherston, convenor of the Building Committee, gave a brief history of the old hall and the circumstances which led to the erection of the new building.

President's Address

The President (Dr Argyle) then gave an address. In 1879 the Victorian Branch, he said, was founded with 62 members, to-day it had 1,185. He then sketched the development of modern knowledge since the Branch was founded, referring in particular to the establishment of antiseptic surgery by Lister. The system came into use in the Melbourne Hospital in the early eighties, and by a process akin to revolution it had now been replaced by aseptic methods, the use of which rendered it possible for a surgeon to operate on every region of the body with practically no risk at all from the operation. He then touched upon some of the developments of bacteriology which had enabled preventive medicine to become a real force in the community. Typhoid fever had practically vanished in large cities. In Victoria in 1878 the deaths from that fever were 50.7 per 100,000, to-day the rate was only 2 per 100,000. With adequate sewerage in the country towns the disease would vanish altogether. Deaths from diphtheria in Victoria in 1878 were 65.4 per 100,000, to-day the rate had dropped to 7 per 100,000. Tuberculosis in 1878 claimed 1,678 per 100,000, to-day only 71.1. Within the same period physiology and pathology, assisted by biochemistry and physical science, had moved forward in no uncertain way, investigators were busy in the diagnostic field, and in epidemic and tropical diseases the work of biological inquiries had reaped a rich harvest. The greatest contribution to medicine by the physicians was the discovery of the x-rays by Roentgen in 1895. It was almost impossible to overestimate the value of the method in both medicine and surgery. No hospital was complete, no textbook up to date, no practitioner safe, if the x-rays were not regularly used as part of the daily routine for the accurate diagnosis of injury or disease. The discovery of radium by M. and Madame Curie in 1898 added yet another physical weapon for the treatment of cancer and allied conditions. Many puzzling diseases of nutrition were now known to be deficiency diseases due to the lack of some element in the food supply. But though much had been done there remained much to do, especially in regard to tuberculosis and cancer. The net result of all the discoveries and activities during the last forty-seven years was remarkable. In Victoria in 1878 the death rate per 1,000 was 14.56, in 1924 it was 10.05. The medical profession in Victoria had done its part in the great war of 966 members, 407 enlisted for active service (about 42 per cent), and of these 43 (10.5 per cent) died on service. One-third of those who remained behind also did war service.

In declaring the building open Dr Argyle used the words of Dr Osborn Taylor to dedicate it: "To the noble profession, whose gospel is the healing of mankind, whose honour is the Hippocratic oath."

The Attorney General (Mr Eggleston), after congratulating the Branch on its acquisition of such a fine home, said that the general community did not fully realize the extent of its indebtedness to the medical profession, or the magnitude of the sacrifices which members of the profession frequently made.

The Lord Mayor of Melbourne expressed the congratulations of the citizens, and Dr C. G. Laws spoke in the name of the New South Wales Branch, of which he is vice-president. Dr Douglas Stephens, senior vice-president of the Victorian Branch, also responded, and Dr J. Newman Morris, on behalf of the members of the Branch, presented Dr Fotherston with a cheque in recognition of his services for the new building. Afterwards a reception was held in the library.

Scotland.

MEMORIAL TO SIR WILLIAM MACCOWEN AT ERSKINE

AT the Princess Louisa Scottish Hospital for Limbless Sailors and Soldiers at Eiskine there was unveiled on June 20th a memorial to the late Sir William Maccowen. As one of the pioneers in the founding of this hospital, Sir William devoted himself with great energy and enthusiasm to the work carried on there during the war, and it was largely to his splendid services and surgical skill that the institution owed its success. The memorial takes the form of a mural tablet, designed by Mr G. H. Paulin, and is placed in the entrance hall of the main building, and upon it due recognition is made, not only of his association with Eiskine, but also of his outstanding achievements and world-wide fame in the realm of surgery. The tablet is of bronze set in marble, and bears the following inscription:

"In honour of Sir William Maccowen C.B. D.L. F.R.S., Honorary Surgeon to the King in Scotland, Regius Professor of Surgery in the University of Glasgow, a world-renowned surgeon, a great man to whom this hospital owes its inception to whose untiring labours its success is due who within these walls, by his skill restored to active and useful lives many of those maimed and broken in the Great War."

Over the tablet was placed a wreath designed by H. R. H. Princess Louise, who had hoped to attend the ceremony, but whose health did not permit of the journey north. In her absence the unveiling was performed by Principal Sir Donald MacAlister, Bt., who delivered a graceful and eloquent oration on Sir William Maccowen and his services to the hospital, in the presence of a large company. Sir John Reid, in handing over the memorial to the custody of the Lord Provost of Glasgow on behalf of the hospital, read a personal letter which he recently received from Princess Louise, in which Her Royal Highness expressed her great regret that she could not attend and take part in the proceedings. "It is a very real disappointment to me," she added, "to have to write this to you, as I have been counting all along on coming to be among you all, who have so kindly wished me to be with you for this occasion at Eiskine House, which I am proud of looking upon as my hospital, for, as you well know, I take a true and affectionate interest in it. It was Sir William's special child, which he created and put his whole heart and soul into." Sir John Reid joined in paying tribute to the work of Sir William, as did also Lord Provost M. W. Montgomery in accepting custody of the memorial. Dr James A. Adams spoke in the name of the medical profession. Dr J. A. C. Maccowen, speaking on behalf of Lady Maccowen and his sisters and brothers, expressed appreciation of the graceful tribute that had been rendered to his father's memoir. In proposing a vote of thanks to the Lord Provost, the Marchioness of Ailsa said the tablet spoke with admiration and gratitude of Sir William's services to the hospital, but the real memorial would be the carrying to completion of the ideal he so magnificently conceived of establishing it as a permanent national institution for the benefit of disabled sailors and soldiers.

WILLIAM AND JOHN HUNTER MEMORIAL AT GLASGOW

The University of Glasgow on June 24th conferred honorary degrees on a number of distinguished men, and afterwards another ceremony took place at which homage was paid to the memory of two great medical brothers, William and John Hunter, who were natives of East Kilbride, the former a student and graduate of Glasgow University. Both proceeded to London, where they achieved great distinction, one as a physician and the other as a surgeon. In common they were creators of great and invaluable museums. William gave to Glasgow University the Hunterian Museum, remarkable not only for collections in anatomy, natural history, and a fine library of books and manuscripts, but also for a world renowned collection of coins. John Hunter, "the pioneer of all that is philosophic in modern biology," presented his museum to the Royal College of Surgeons of England. The memorial to the brothers has been erected in the University grounds on a lawn facing University Avenue, and forms a striking piece of architecture. Built of white stone, it is enclosed in a three-sided rectangular stone court formed by low walls having stone ledge seats, and is approached by a short flight of steps. Rising from its rear wall is the main feature of the monument—a squat stone with two shoulders of panelled wall. On the upper part of the centre stone are the arms of Glasgow University, below which is the following inscription:

"In gratiam memoriam fratrum de scientia naturali et medendi arte Optime meritorum Gulielmi (1718-1783) et Johannis Hunter (1728-1793) quorum uterque famæ venitor aeternae hic collegium chirurgicum Londini regum ille Glasguae alumnus idem et dator matrem studiorum Universitatem musæo condito ornavit

On either side of the main piece are chiselled heads of the two brothers, while on the east and west ends respectively of the higher walls are the arms of the Royal College of Surgeons of England and the Royal Faculty of Physicians and Surgeons of Glasgow. The origin of the memorial dates back to 1893, when the idea was first mooted by the late Dr. George Ritchie Mathew when publishing a biography of the two brothers. Unfortunately, before any steps could be taken in furthering the idea Dr. Mathew died, but his suggestion lived, and has now matured in the present memorial. Mrs. Mathew, his widow, who strongly supported the proposal and has been instrumental in having his wishes carried out, had the privilege, as was most fitting, of unveiling the monument. On behalf of the subscribers Dr. David Murray, chairman of the Memorial Committee, formally asked the University authorities to accept custody of the memorial, "to commemorate two Lanarkshire men who by their own genius, without the aid of powerful friends or by the chances of fortune, attained to the highest eminence, and from whose careers we should learn that whatever is to be of enduring value must be the outcome of individual effort, of self-reliance, and of unremitting labour." Sir Donald MacAlister gratefully accepted custody of the memorial in the name and by the authority of the University Court. In so doing he said that the University, though its field of service was wider than the city, the west country, or the Scottish homeland itself, had yet a special relation and responsibility to these. It had to keep before the eyes of the citizens of Glasgow, and of actual and potential students who frequented its precincts, visible tokens of the things it stood for and sought to foster. Its buildings should be stately and suggest the dignity of learning. Its grounds for health, exercise and recreation should be ample and seemly, and so manifest the fostering care of Alma Mater for the well-being of her alumni. Its public museums should be comprehensive and well furnished, that minus the most various might find therein matter to stimulate interest and evoke intelligent inquiry. Its portraits and memorials of the worthies who were exercised within its walls should be many and conspicuous, that examples of excellence in their several kinds might be held up before all, and set forth visibly as the abiding heritage of their successors for encouragement and imitation. This memorial to the brothers Hunter enriched the University in more than one of these respects. It told in especial of two humble Glasgow students who by dint of

industry and native talent, rose to fame as leaders of science and benefactors of their kind. It said with silent eloquence, "What Glasgow students did, Glasgow students can do." For this additional stimulus to higher endeavour the students and teachers of the University thankfully acknowledged their debt to the contributors. Sir John Blind Sutton, Bt., President of the Royal College of Surgeons of England, who at the graduation was the recipient of the degree of LL.D., spoke as representing John Hunter, and Professor F. K. Monro, President of the Royal Faculty of Physicians and Surgeons of Glasgow, as representing William Hunter. In doing so both paid tribute to the memory of these great medical brothers, who each in his own way had won fame, and whose names are still held in reverence.

EFFECTS OF THYROID EXTRACT ON ACID FOWLS

At a meeting of the Royal Society of Edinburgh on June 22nd, when Principal Sir Alfred Irving was in the chair, a paper was contributed by Dr. I. A. L. Crow, director of the Animal Breeding Research Department of Edinburgh University, on rejuvenation of the aged fowl through thyroid medication. Dr. Crow said that as a fowl got old its plumage got lighter and its fecundity decreased. Experiments had shown that the cause of this was, possibly, a progressive inefficient functioning of the thyroid gland. Desiccated thyroid had been given to old fowls, with the result that all the birds became rejuvenated, the plumage of the cocks becoming similar to that of normal hens, whilst the egg yield of the hens was increased to a remarkable extent.

GRANT TO ROYAL SIMPSON MEMORIAL HOSPITAL

On June 24th a deputation from the Royal Maternity and Simpson Memorial Hospital, Edinburgh, met the Lord Provost's Committee of Edinburgh Town Council to support an application for a grant towards capital expenditure. The deputation explained that property in the neighbourhood of the hospital had recently been purchased at a price of £650, and that the cost of alterations necessary to adapt this property for the purposes of the hospital would be about £950. The Lord Provost's Committee agreed to recommend that the town council should grant £950 to the hospital for this purpose.

CENTRAL MIDWIVES BOARD FOR SCOTLAND

At a meeting of the Central Midwives Board for Scotland on June 24th Dr. James Haig Ferguson was in the chair, and Sir Archibald Buchan-Hepburn, Bt., was appointed deputy chairman in place of the late Dr. Michael Dewar. Intimation was made that the Scottish Board of Health had approved the new rules for extended training of midwifery nurses, which come into force on May 1st, 1926, and will apply to all persons commencing midwifery training thereafter.

Ireland.

IRISH FREE STATE PENSION RIGHTS
Important Notification

Medical officials under county health boards and other local authorities should bear in mind that if they desire to avail themselves, for pension purposes, of Section 8 of the Local Government Act, 1919, they must notify their local authorities of their intention at a date not later than July 25th next. The following summary of the pension rights of medical officers under the Acts of 1919 and 1925 has been addressed to Local Medical Committees by the Irish Medical Society. What the medical officers affected have to consider is whether in each individual case the benefits of Section 8 of the Act of 1919, and in certain cases the benefits of the Local Government, 1898 Act, gave more favourable terms than the benefits under the Act of 1925. (1) Generally, the older provisions appear more favourable, but we prefer not to lay down any hard and fast rule, as there may be some cases in which the terms of the more recent Act would operate to greater

advantage than those of the earlier Acts. We desire to call particular attention to the fact that there is no scale save a maximum one prescribed by the 1925 Act. Subject to this the Minister has arbitrary power. (2) Under Section 8 of the Local Government Act, 1919, the fact alone that a medical officer is 60 years of age, and has served as an officer of a local authority for not less than twenty years, entitles him, with the consent of the Minister, (i) to resign his office, and (ii) to receive a mandatory pension on a defined minimal and maximal scale. No medical certificate of permanent disability is required with these conditions. Under the Local Government Act, 1925, a medical officer to resign under the conditions (just mentioned) of the Local Government Act, 1919, must have attained 65 years of age and must have twenty-five years' service—that is, under the 1925 Act, an extra five years is added to each condition. The recent Act (1925) would be more advantageous (a) in the case of women doctors who, on marriage, would resign their offices, (b) in some respects in the case of a medical officer who had served in a pensionable office outside the area of his present pensioning authority—that is, the County Health Board. The following draft letter might be employed by medical officers who prefer to retain their rights under the Act of 1919.

Address and Date
Board of Health

To the Secretary

Sir,
I beg to notify you for the information of Board of Health that it is not my intention to avail myself of the provisions of Part 4 of the Local Government Act 1925 with the exception of the several sections which by Section 43 of that Act are made applicable to an officer making the election which I am doing.

I am Yours faithfully

England and Wales.

THE LONDON UNIVERSITY SITE

THE correspondence between the Principal Officer of the University of London and the Treasury, which is printed at page 43, would, if taken literally on its face value, appear to amount to a final decision that the University headquarters shall not be established in the Bloomsbury district, as was proposed some time ago, when the Government, through the mouth of Mr H A L Fisher, then President of the Board of Education, made a definite offer of a site, subject to certain contingencies set out in the correspondence. Lord Haldane, when opening the new headquarters of the National Union of Students of the Universities and University Colleges of England and Wales, in Endsleigh Street, Bloomsbury, last week, said that the Royal Commission on University Education in London, of which he was chairman, had, among other things, reported that London must have a university centre, and that the centre should be Bloomsbury. There was no situation in London comparable to that neighbourhood for the home of the University, for headquarters, for lecture rooms, or for a club house and an assembly place for students. The University would not achieve success unless it avoided the extreme act of folly which it seemed about to commit in not setting to work to get a constitution for the University. The Union he was addressing was formed three years ago, and already includes about 30,000 undergraduates. The new building provides an adequate central office and club rooms. A university, Lord Haldane said, was essentially dependent on its atmosphere. In the Union there was a body of students, women as well as men, who represented the university atmosphere from different parts of the world. University students, men and women, wherever they might be, whether in Washington, Tokyo, Berlin, or Paris, thought alike, provided only there was a sufficient height of knowledge. London, the greatest city in point of numbers in the world, and not diminishing in importance, was without a proper university. There were in London many colleges, several of which exceeded

in size universities in the provinces, but they were not brought together under one roof, and it was not easy to bring them under one roof. He himself had been at work on the problem for over thirty years.

GUY'S HOSPITAL MEDICAL SCHOOL

The annual Guy's Hospital garden party—a pleasant event in pre-war days—was revived on June 29th when H R H the Duke of York, deputizing for the Prince of Wales, who is president of the hospital, distributed the prizes to the successful students in the medical school. The Duke was received by the Treasurer of the hospital (Mr F P Whitbread), the Vice-Chancellor of the University of London (Professor Ernest A Gidner), and the members of the hospital staff, and after a visit to the concert-room for certain presentations, he proceeded to the physiological theatre, where a distinguished company had assembled. The Treasurer extended a hearty welcome to His Royal Highness, and referred to the intimate way in which the progress of the hospital, now in its bicentenary year, had been bound up with the progress of the medical school. The Duke did not address the assembly, but contented himself with distributing the fourteen medical and seven dental prizes and scholarships and individually congratulating the successful students. One remarkable and probably unprecedented success was the winning of the Treasurer's gold medal for clinical medicine and the Treasurer's gold medal for clinical surgery, as well as the Beauchamp prize for pathology, by the same student—Mr D W C Northfield. The brief proceedings concluded with an enthusiastically accorded vote of thanks, moved by Dr Finckh, senior physician to the hospital, who referred to the great traditions of Guy's and the generations of good doctors and wise and humane men who had gone forth from the school. The Duke of York afterwards visited the Henriette Raphael Nurses' Home, where work contributed by the Ladies' Association (of which the Duchess is president) was on view. An interesting collection of antiquities was arranged in one of the departments, it included relics of Thomas Guy and some of the earliest books and prints connected with the hospital. The wards, museum, and laboratories were open to inspection, and each visitor was handed an extremely well got up pamphlet, which contained not only the order of proceedings, but also a history of and guide to the hospital.

DEPUTATION TO THE MINISTER OF HEALTH FROM THE LONDON COUNTY COUNCIL

A deputation from the London County Council on various matters connected with health administration in London was received by the Minister of Health on June 8th. Mr Neville Chamberlain, in the course of his reply, said that Poor Law reform was part of the programme of the Government for next year, conditional, however, upon the passing during the present session of the Rating and Valuation Bill. One of the questions which would then come up for consideration was the extent to which the present Poor Law infirmaries could be used for the accommodation of advanced cases of tuberculosis, on the surface it seemed as if they would be very suitable, but he thought it was clear that in any satisfactory provision for the institutional treatment of tuberculosis in London there must be some central body capable of taking a survey of the needs of the whole area and seeing that those needs were properly and suitably provided for. This did not necessarily imply with it central administration of the units of institutions—a matter on which he would not like to commit himself at the present time. On another aspect of the tuberculosis problem—that of after-care—the Minister said that he regarded the experiments that had been carried out at Papworth and Preston as extremely interesting and valuable, but they could not provide a complete solution of the problem. There were, however, other experiments in progress or in contemplation for the setting up of workshops in large towns which would be under medical supervision and would work under such conditions as might be laid down by medical advice, but which he did not think could be run without a subvention. He was in communication with the Treasury on the matter, and if he was fortunate enough to soften the heart of the

Chancellor of the Exchequer he might be able to put forward a scheme for grants in aid for certain experimental stations. He also spoke on the subject of refuse disposal and drainage and indicated that he would take steps to secure expert inquiry to see whether certain views put forward by the deputation could be met.

Correspondence.

MEDICAL EDUCATION IN WALES

SIR,—As one who has taken a deep interest from its inception in the proposal to establish a really national Welsh School of Medicine, I have read Sir Isambard Owen's letter in your issue of June 20th (p. 1150) with some surprise. I am surprised both by what is said in that letter and by what is omitted from it.

1 Sir Isambard Owen writes "The policy of separating the Cardiff School of Medicine from its parent college was not a recommendation of the recent Royal Commission" that policy, he states, originated with the University and was dictated by financial factors. Sir Isambard Owen omits any mention of the strong move to make a National School of Medicine which developed before the appointment of the Royal Commission. That was, and is, an important factor in the situation, and the final recommendation of the Royal Commission is sufficiently explicit.

216 The endeavour at once to give the School of Medicine a national status and to recognize the special interests of the University College at Cardiff produced a highly complicated plan which was admitted by the Departmental Committee to be only the best that could be devised under disadvantageous conditions. After a careful consideration of the various suggestions in relation to our general task we have decided to recommend the mere simple plan suggested to us by Sir Isambard Owen of organizing the Medical School as a constituent College of the University to be governed under the University by a Council and Senate of its own.

I have italicized the last lines of this quotation because I find it difficult to reconcile them with Sir Isambard Owen's assertion that the policy of separating the Cardiff School of Medicine from its parent college was not a recommendation of the Royal Commission. Any man is as well entitled to change his mind as any woman proverbially is to change hers, but Sir Isambard Owen seems to have executed a complete volte-face.

2 Sir Isambard Owen does not mention that the new scheme of erecting the school as a "school of the university" and not as a "college of the university" was in the first place suggested by the Senate of the College at Cardiff itself. The University Council, in proposing the new scheme of constitution, is in effect bowing to the suggestions of Cardiff College, of the council of which Sir Isambard Owen is a member.

3 Sir Isambard states that the article in the *BRITISH MEDICAL JOURNAL* (which he is criticizing) "seems to suggest that this scheme [that is, the scheme now proposed by the University Council] has the approval of the faculty of medicine of the university, my information is that it has not yet been before the faculty." Sir Isambard Owen is in error when he suggests that the article in the *BRITISH MEDICAL JOURNAL* seems to suggest that the scheme has the approval of the faculty of medicine, although no doubt it would have that approval if submitted to it. The article in the *BRITISH MEDICAL JOURNAL* states quite correctly that the original recommendation of the Royal Commission (in favour of separation as a "college") has been endorsed by the faculty of medicine. It will, perhaps, be a sufficient indication of the way in which the matter is being dealt with by Sir Isambard Owen and his colleagues on the council of Cardiff College if I point out that the college has come to a decision against the scheme, without even taking the opinion thereon of its academic bodies.

4 Another cause of surprise to me is that Sir Isambard Owen, though he refers to the opinion expressed by the Vice-Chancellor of the University of Liverpool in a communication to the *Western Mail*, does not refer to the views previously set out in an article in the same newspaper (February 7th, 1925) by Sir Charles Sherrington, Professor

of Physiology in the University of Oxford, and President of the Royal Society.

Dealing first with the word "separation" as applied to the Medical School, Sir Charles Sherrington said that it might suggest that the school would suffer thereby. It was not, he said, perhaps sufficiently realized that the question of separation will not affect the present academic arrangements, and that those who opposed separation on this ground did so without knowing the true facts of the case. The supreme academic authority of the University is, he pointed out, the Academic Board—composed of representatives of all the faculties of the university. The present academic relationship of the School of Medicine to the University on the one side and to the University College at Cardiff on the other, will remain unaltered in the independent School of Medicine.

He then passed on to consider the question of the independent colleges which would accrue from independence. He wrote as follows:

In the first place there will be a more efficient administration of the school, which has to report to (and is subject to) the council of Cardiff College, which again on many matters has to receive the consent of the council of the University. As the Board of Medicine the College Council and the University Council all have their own administrative machinery and sub-committees it is not difficult to see that the present administration of the school is very complicated and slow in action. The proposal to give the School of Medicine independence within the University is essentially a proposal to make its Board of Medicine an effective administrative body with power similar to that of the councils of the constituent colleges of the University. I venture to say that the independence of the school does not entail further academic separation but does involve a more efficient administration of the school.

Under the constitution in favour of which he was writing, the status of the Medical School would, he said, be that of a school of the university carrying on its work in complete harmony with the University College of Cardiff, but functioning as a unit of the university rather than as a department of a constituent college. There was no reason, he believed, why this arrangement of itself should affect academic intercourse, for at Oxford and Cambridge the measure of independence enjoyed by the colleges and the school of medicine did not affect intellectual and take place of how this might be brought about did not depend upon the question of governance. The University of Wales, he continued, occupied a unique position among the universities of Great Britain, not only on account of its federal character, but also because it was a national university in a sense not true of any other British university. It was a single expression of ideals and aspirations of a whole nation, it had several constituent parts, but the university itself was one and undivided. The highest interests of the medical school demanded, in Sir Charles Sherrington's opinion, that it should be associated directly with the national university rather than with one of the constituent parts of that university. This claim was "not only inherent in the federal character of the university, but also records with the importance of medical science as a branch of learning and with its vital bearing upon the well being of the community." The idea of a school of medicine for the whole of the Principality had captured the imagination of the Welsh people, if their hopes were to be realized the young institution must be given full freedom to develop. Complete incorporation of the medical school with the Cardiff College would prevent it from developing on its own lines, would lead to a conflict of interests, and would saddle it with the necessity of submitting to College exigencies. Sir Charles Sherrington concluded his article with the following words:

The nature of the constitution of the University of Wales as well as the national status of the school in my opinion point unmistakably to the recognition of the school as an independent unit of the University. Given the support of the Welsh people and given full freedom of action in framing and directing its own policy it is my hope and expectation that the School of Medicine will go from strength to strength and may come to rank with the finest and most up to date schools in the world.

The real factor in the situation is this that as things

are at present in Cardiff it will not be possible to develop a first-rate school of medicine unless it is separated from the local college and placed directly and fully under the University of Wales itself—I am, etc.,

Leechard, Cardiganhire June 27th JOHN LYNN-THOMAS

THE DIPLOMAS OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON

SIR,—In your notice of the death of Dr. Edwin John Slade-King, which appeared in the JOURNAL last week (p. 1200), you omitted to mention the fact that Dr. Slade-King was the last medical man left who held the diploma of "Extra Urbem Licentiate" of the Royal College of Physicians. The power to grant the diploma of "Extra Urbem Licentiate" was secured to the College by the statute of 14 and 15 Henry VIII (1522-23), and brought under the authority of the College all those who practised medicine in England, with the exception of Doctors of Medicine of Oxford and Cambridge. Before this statute was enacted the College had authority only over those who practised medicine in London and seven miles round. When, however, the Medical Act of 1858 came into force, this provision in the statute was repealed, and the grade of "Members of the College" was instituted in place of the "Licentiates" and "Extra Urbem Licentiates." Under the Medical Act of 1858 a new grade of "Licentiate" was established which referred to those who passed the qualifying examination now known under the letters L.R.C.P. Dr. Slade-King was one of the last to take the "Extra Urbem Licentiate." This he did in 1857, and with his death the diploma becomes extinct—I am, etc.,

London W 1 June 26th

ARNOLD CHAPLIN

PERINEAL DRAINAGE AND PROSTATECTOMY

SIR,—Mr. William Billington has raised (June 20th, p. 1150) a very interesting topic—namely, perineal drainage in internal urethrotomy and prostatectomy. With regard to perineal drainage in internal urethrotomy, does Mr. Billington enquire this out in all cases? Personally I feel that internal urethrotomy is an operation which has justified its existence by time, experience, and results, and should a case demand perineal drainage, then I would consider it one for external urethrotomy and not internal urethrotomy. The cases of stricture in which I have employed perineal drainage have been those complicated with severe cystitis and a type rarely seen in this country, but frequently in the East—namely, when the perineum is a mass of sinuses and fistulae and dense fibrous tissue. In the latter type external urethrotomy with drainage of the bladder is the only way by which the sinuses can be dealt with and the condition cleared up.

I have on a few occasions done median perineal lithotomy in children for stone when, owing to total lack of nursing and having the bare minimum of instruments with me, no other course was available. Necessity knows no rules, with the open desert as my operating theatre and the beautiful crystal an and "Allah" as my helpers, the results were delightful. Drainage was perfect.

With regard to perineal drainage in prostatectomy, I feel that this is adding another complication to an already sufficiently complicated operation. We must remember that an enlarged prostate is not an affection of the prostate alone, but a symptom of a generalized condition in individuals who are not only past the autumn of their days, but are fast approaching the winter.

Prostatectomy is a serious operation in the hands of even the expert, with its mortality rate nearer 20 per cent than 10 per cent, in the hands of the general surgeon the mortality must be far higher, and if perineal drainage will lower this mortality rate, then by all means let it be fully considered. I have only on one occasion used perineal drainage, and my reason for then doing so was the enormous cavity left after the removal of a big prostate with much sepsis of the bladder, but instead of cutting down on to a Wheelhouse's staff I pushed a long sinus forceps through the prostatic cavity into the perineum and

cut down upon that, using the ends to drag up the drainage tube into the prostatic cavity.

I am convinced that the mortality rate of suprapubic prostatectomy can be still further decreased by more attention being paid to the renal excretion tests. I rely on the urea excretion and phenol sulphonephthalein tests, and also very largely on the general condition of the patient himself. The subjects of prostatectomy will not tolerate long waits in cold and draughty corridors and a subsequent prolonged operation. Rapidity with the choice of a suitable anaesthetic and the production of as little shock as possible are among the many essentials for a lessened mortality rate. I have used gas and intratracheal oxygen for my last two cases, and I have been more than pleased with the complete relaxation obtained and the absence of vomiting and of post-operative shock.

SIR JOHN LYNN-THOMAS (BRITISH MEDICAL JOURNAL, June 27th, p. 1194) mentions the lower rate of mortality from the perineal operation. This may be so, but are the end-results satisfactory? The occasional drainage down to the nerve supply of the compressor urethrae muscle in this operation, with the resulting incontinence, leaves the patient in a worse condition than when he had the original disease. I have lately met with an instance of a patient who had undergone perineal prostatectomy and now spends his time going from hospital to hospital, and from surgeon to surgeon, seeking relief from this terrible affliction.

There is nothing worse from a public standpoint than to operate on doubtful subjects. In doubtful cases permanent suprapubic drainage properly done and a suitable apparatus fitted is a far better procedure than to submit many decrepit old men to the risks of so serious an operation.

I quite agree with Sir John Lynn-Thomas when he states that "we have to look out for weakness in the minute details of the plan of attack." A still greater consideration is the patient himself—I am, etc.,

London W June 27th

THOS. CAREY EVANS

URINARY INFECTIONS

SIR,—Dr. Sangumetti (June 27th, p. 1168) discusses lavage of the bladder with a weak solution of collargol in certain urinary infections. He apparently advocates this method of treatment for acute and chronic conditions indiscriminately, for many different types of infection, and even in cases of a definitely descending character.

In acute infections vesical lavage is usually quite unnecessary and may be positively harmful. The majority of acute cases clear up rapidly, if the patient is put to bed, the bowels attended to, and the urinary tract washed out in the natural way with copious quantities of bland drinks. Potassium citrate followed by hexamine with acid sodium phosphate may be useful in some cases, while sandalwood oil has an almost magic effect if the infection is due to the staphylococcus.

Lavage is undoubtedly useful in chronic infections when the bladder is not emptying itself effectually. If it is employed in chronic infections great care must be taken to exclude the possibility of the underlying condition being tuberculosis, which contraindicates irrigation.

Vesical lavage in cases of definite descending infection would appear to resemble cleaning the ball and leaving the living-rooms untouched.

When irrigation is necessary, a solution of silver nitrate is much less messy than one of collargol, and probably just as effective—I am, etc.,

London W 1 June 27th

W. K. IRWIN

THE DIAGNOSIS OF PNEUMONIC PLAGUE

SIR,—The great importance of the differential diagnosis of pneumonic plague and plague pneumonia from the point of view of prognosis and prevention cannot be overestimated by workers amidst plague, as pointed out by Dr. N. A. Dree Sharp of Lagos in your issue of December 27th, 1924 (p. 1216). It is surely no satisfaction to anyone concerned with a case of the former to establish its diagnosis after the patient's death. Unfortunately, however, medical literature abounds with expressions like pneumonic plague and plague pneumonia, septicæmia

plague and plague septicaemia, that are loosely applied and held to be interchangeable. And thus confusion becomes worse confounded, inasmuch as these terms are neither identical nor interchangeable.

It is obviously forgotten that bubonic plague is essentially and primarily an infection of the lymph channels, and glands, and remains so in about 30 to 40 per cent of cases admitted to hospital in Bombay. Infection of the blood and internal organs—that is, *plague septicaemia*—occurs at a later stage in about 60 to 70 per cent, and is a secondary manifestation. So also is the advent of pneumonitis, which has been recognized as plague pneumonia.

On the other hand, septicaemic plague is a primary infection of the blood without the intervention of the lymphatic system, and is therefore a far graver infection. Here, too, pneumonitis may supervene as a secondary pneumonia, it is often mistaken for pneumonic plague in the absence of examination of the blood. True pneumonic plague, however, occurs from direct infection of the respiratory tract either from droplet infection from a patient or from a localized focus in the tonsils. I suggested the possibility of the latter mode of infection in 1909, and it was subsequently confirmed by the observations of the Plague Commission in Manchester during the epidemic of pneumonic plague in 1911.

The early diagnosis of pneumonic plague and plague pneumonia (secondary) is at times beset with considerable difficulty in the absence of physical signs during life, and also of the characteristic sputum. No amount of painstaking examination gives any indication of their presence. The physician can therefore only infer its presence on account of the prevailing epidemic. High temperature, exaggerated pulse and respiration ratio, extreme restlessness and delirium, pain and sense of constriction in the chest dyspnoea, and at times cyanosis, are the only indications to guide him or raise his suspicion. Death is rapid—within three to four days. Where, however, buboes exist the above may be considered as positive signs of plague pneumonia. The character of the sputum, when it does appear, is by no means constant. It may be purulent haemorrhagic, or pellets of coagulated blood, or bright red frothy blood-tinged mucus. Any of these characteristics may not develop till shortly before death. The clinician is thus greatly handicapped. At the autopsy, however, deep-seated and localized foci of infection or infarcts, or even solid consolidation, may be found and give pure cultures of the *Bacillus pestis*.

Prognosis, however, differs. Extensive observations at the Bombay hospitals throughout a series of epidemics have shown that cases of plague pneumonia recover to the extent of 10 to 15 per cent provided the lung infection is strictly localized. Pneumonic plague—and, for that matter, septicaemic plague also—are both equally fatal, the mortality being 100 per cent. In my experience, extending over twenty-seven epidemics of plague, I have not observed a single bacteriologically verified case of pneumonic plague recover. The single exception was one in which there existed a symbiosis with the *Bacillus pyocyaneus* in the lungs. This combination was established by frequent cultural and animal experiments with the sputum, until at last the organisms finally disappeared from it.

The above facts thus indicate that small blame should attach to any clinician if he fails to verify the presence of pneumonic plague or plague pneumonia during life. Geimino to the subject, an isolated instance of plague pneumonia causing infection of the bubonic type may be here quoted. An English plague nurse working at the Arthur Road Hospital had severe coryza with injected eyes, and was advised to rest. Whilst bending over a bubonic plague patient to feed him he happened to cough, and some sputum went into one eye. Within two days she developed parotid and cervical buboes, with considerable oedema of the neck and pharynx, oedema of the glottis soon supervened, and death occurred within five days. This case illustrates the possibility of such a contingency—
I am, etc.,

N H CHOKSY MD, F.C.P.S.,
Late Medical Superintendent Arthur Road and
Maratha Plague Hospitals

Bombay Feb 7th

STATICS OF THE SMALL PLYVIC VISCERA
Sir,—I am sorry that the reviewer of vol. II of my *Statics* (June 27th, p. 1176) should think it a sin for an author to believe in himself. The late Sir Henry Duthie once said to me, "If an author does not believe in himself, who can be expected to believe in him?" And, of course, no worker is going to the pains of writing a book, and much less of getting it published, unless he believes that his point of view materially and in an important manner differs from current opinion. If I am wrong in stating that "many operating gynaecologists are clearly at sea" in the matter of prolapse, I am clearly at a loss to know how I am to be taken into account by the majority of these surgeons. I am sorry, if I can be shown to be wrong I will gladly retract those statements. They were at least made in good faith. But in this respect I remind your reviewer that even as late as last April we heard in exposition on prolapse in which not only the work done on the pelvic floor musculature in this respect was completely ignored, but which imputed prolapse to merely local lesions, and consequently did not take into account the conception "that man is individual." The connective tissue hypothesis does not explain how it is that prolapse—or, as I think it would be better called, "puccendal hernia"—is related to the intra-abdominal pressure (a pressure affecting the whole individual) as other herniae, or how it is related with general metabolism, as shown by its common use in later life. But because I believe so—and show it is so—your reviewer is vexed with me.

Your reviewer accuses me of implying throughout my book that I alone know anything of prolapse. I am sorry, too, if that is so, I was not aware of it, if it be so it was not intentional. I can at least reply that your reviewer, throughout the major part of his review, seems to imply that he knows as much or more of prolapse. Yet as a reviewer he fails in his main and primary task—that of criticism. He, indeed, is critical, but it is of the author, not of the argument. Had he shown that my argument is erroneous he would have put your readers, and more especially myself, under a greater obligation—I am, etc.,

Rugby June 27th

BRITISH MEDICAL WOMEN IN INDIA

Sir,—Having recently been engaged in administrative work in India I can perhaps supply some of the information "Medical Woman" (June 27th, p. 1195) asks for. The population of India is so vast, and the prejudice among Indian women against the attendance of male doctors is so widespread, that the field of usefulness for women doctors is almost unlimited. Unfortunately your correspondent is right in thinking that the opportunities for British medical women are really few.

Religious prejudice and social custom in India are so strong that a newcomer, ignorant of both, and endeavouring to form a private practice, would be seriously handicapped. Moreover, owing to the poverty of the people, she could not hope to make a suitable livelihood outside the large towns.

The Women's Medical Service for India offers good prospects, but it is small and not likely to offer more than two or three openings a year for British medical women. The field in connexion with mission hospitals is larger, but the salaries are small, and special interest in mission work is, of course, required by the societies.

Other appointments are occasionally offered in connexion with Indian States and municipalities. Sometimes a European is asked for, but even then a newcomer in the country would be at a disadvantage, and the employers are usually unwilling to enter on negotiations with people at a distance, which may end in nothing, or to meet the cost of passages.

If a young medical woman had friends in a large town in India and had sufficient capital for a few years' subsistence, she might go out, and would probably be well come as an honorary worker in the women's hospital. She would thus gain experience of the language and country, and might hope to do well later in private practice.

She must however, be competent, and have some experience of her profession. Even if she does not desire private practice she is far more likely to obtain a hospital appointment if she is on the spot, has some knowledge of the country, and can be interviewed.

The Secretary of the Countess of Dufferin Fund, Delhi and Simla, is always glad to assist medical women in India with advice regarding possible openings. I believe also that some of the large women's mission hospitals are willing to appoint young British medical women as house surgeons for a year or two without permanent service. This would give excellent opportunities of acquiring knowledge of the country and tropical work.—I am, etc.,

M I BALFOUR, M.B.,
Late Secretary of the Countess of Dufferin
Fund India

Edinburgh June 29th

FRACTURE OF BOTH PATELLAE BY MUSCULAR ACTION

SIR,—The cases of simultaneous fracture of both patellae reported by Mr Twistington Higgins and Mr W M Cummins in the *BRITISH MEDICAL JOURNAL* of May 30th (p 1006) and June 6th (p 1062) respectively, have reminded me of a similar case which occurred in Cairo in 1915, and which may be of interest.

I was present at an evening performance at a place of entertainment, and a dance performed by an Armenian girl was taking place. During one of the steps the girl collapsed, and it was seen that she was unable to rise and in great pain.

I was accompanied by a friend, Dr Kinnaird, and when the manager came forward and asked if a doctor was present, my friend went and attended the case. He afterwards informed me that both patellae were fractured and that he attributed the fractures to muscular action.

In spite of the almost unanimous opinion of the many Egyptian medical men who soon collected, Dr Kinnaird subsequently wired both patellae, and the woman made an excellent recovery. The "girl" in question appeared, when off the stage and devoid of make-up, to be nearer 40 than 30 years of age.

It was not noticed that great effort was made, or that the step performed at the time of the fracture demanded extraordinary exertion, and the collapse of the woman was a great surprise to the onlookers.—I am, etc.,

London W 14 June 26th

P J SIMPSON, F.R.C.V.S.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT]

AFTER debating unemployment on June 29th, when a vote of censure on the Government was defeated, the House of Commons has devoted the rest of this week to the Widows, Orphans and Old Age Contributory Pensions Bill, which has been considered in Committee. The text of the Government's Unemployment Insurance Amendment Bill has been issued.

The Medical Committee of the House of Commons, which met on June 29th, when Dr Tiernantle was in the chair, decided to meet again specially on July 2nd to receive a report from the party of medical members of Parliament who had been to Geneva to investigate the Spallinger treatment for tuberculosis. Sir Henry Craik pointed out that announcements had appeared in the lay press describing the party as a subcommittee of the Medical Committee, and announcing that it had been favourably impressed by what it saw. The truth was that the party were not selected or deputed by the Medical Committee, and he protested against a statement having been made before the committee had received a report from the party.

The committee briefly discussed the recently issued Treasury minute on the new Committee of Civil Research, and Dr Tiernantle reported that the Prime Minister had informed him that the appointment of this committee and its work would not come under the review of the House of Commons on any estimate.

Safety in Aviation—Captain Guest opened a short debate on fatal accidents in the Air Force and the high premiums charged for insuring the lives of flying officers. He said the risks were taken between the ages of 17 and 28 in the main and twenty years was the extreme flying life of the average officer. Since 1922 the number of flying accidents had been about 120 and he suggested that the Government should organize a compulsory

insurance scheme. The Secretary for Air, Sir Samuel Hoare, said that, judged by the number of flying hours the number of fatal and other accidents tended to decrease every year. The policy of the Air Ministry was that every individual regularly engaged in flying duties should be supplied with an Irvine parachute, and that there should be parachutes available for each aircraft up to the full number of passengers carried besides the pilot. In addition there would be a 25 per cent supply of spare parachutes. The experience of the United States in parachutes had been instrumental in saving a substantial number of lives during the last eighteen months. The Air Ministry was issuing instructions that no parachute descents should be made in bad weather. Descents from aeroplanes were safer than from kite balloons. The Air Ministry was hurrying the delivery of parachutes. He was supplying the Life Offices Association with statistics on air risks, and hoped a reduction of the life insurance premiums for airmen would be arranged.

Removal of Bethlem Hospital—On the London County Council Money Bill Dr Haden Guest drew attention to the condition of the Zoar Street area of North Southwark. There were 165 persons to the acre in Southwark as a whole, but the death rate had gone down from 21.4 in 1903 to 14.2 in 1924. In 1903 the death rate for the Zoar Street area was 40.3 and in 1924 it was 26.6. Certain factors connected with the buildings and with the arrangement of the courts and alleys of that area made its death rate twice as heavy as in other parts of Southwark. A medical report said that the physique of the adults in the area was poor but that the children were in a better condition. To relieve congestion on this area and in Southwark as a whole there might soon be available the site of the Bethlem Hospital with an open space of 13 or 14 acres around it. The hospital authorities had decided to move to a site outside London, and to sell the Southwark site for a commercial price. They were precluded from doing that without bringing a bill before Parliament and a bill for the purpose had already been read a second time in the House of Lords. He advocated the use of the Bethlem Hospital site for the most part as a public open space and for the rest for working class dwellings. The bill was read a second time.

Medical Services in West Africa—On June 29th Mr Amery told Lieut Colonel A. McDouneil that the estimates for the four West African Colonies provided for a total of 246 qualified medical officers. There were at present thirty-two vacancies after allowing for selected candidates at present under instruction in tropical medicine. In the East African Medical Service which included the medical staff of Kenya, Uganda, Nyasaland, Zanzibar, Somaliland, and Tanganyika the authorized strength was 152. There were seven posts unfilled. The medical department of Northern Rhodesia had an establishment of thirteen medical officers, and there was one vacancy.

Ambulance Service in London—On June 29th Dr Little asked the Minister of Health if the recommendations of the Ambulance Committee of King Edwards Hospital Fund had received his consideration. Mr Neville Chamberlain replied that so far as these recommendations could be dealt with by administrative action they had been put into operation. So far as they required legislation they must await the general measure of Poor Law reform which he had in contemplation.

Doctors Cars and Obstruction—Mr N. McLean asked the Home Secretary whether he was aware that regulations existed which rendered doctors liable to prosecution if they left a motor car unattended in the street, and whether he proposed to issue a regulation exempting them when these circumstances arose in the course of their professional duties. Sir W. Joynson-Hicks said that medical practitioners were not exempt from the ordinary law as to driving offences, and the Minister of Transport did not think it practicable to make exceptions to the existing law or regulations in favour of any particular class of persons. The police exercised discretion in regard to prosecuting for obstruction when it was caused by a doctor's attendance on a patient. Mr McLean asked whether the Minister was aware that practitioners visiting sick patients had been summoned, and that only owing to the good sense of the magistrates were they saved from a conviction. He asked whether the Minister would not make some regulation which would enable a medical practitioner to have the particular privilege when visiting sick people of leaving his car unattended. Sir W. Joynson-Hicks said he did not think it desirable to make such a regulation. The police acted with discretion. Quite conceivably it might happen that someone was ill in Bond Street and a medical practitioner might block the whole place for a couple of hours.

General Nursing Council—The House of Commons has set up a Select Committee to consider the rules of the General Nursing Council on the prescribed training for nurses and the reservation of seats on the council for matrons. The Committee has power to send for persons, papers and records. Its members are Sir Richard Barnett, Sir George Berry, Mr Rhys Davies, Mr Fisher, Dr Tiernantle, Sir Charles Forrester Waller, Mr G. Hurst, Sir Richard Luce, Colonel Sinclair, Miss Wilkinson and Mr P. Wilson.

Institutional Treatment of Encephalitis Lethargica—In answer to Dr Haden Guest Sir Kingsley Wood said the Minister of Health was advised that no special institutional provision was required for cases of encephalitis lethargica in the acute stage. Such cases might in general be properly admitted to isolation hospitals, infirmaries or general hospitals. The provision of a special institution for the reception of children suffering from the after effects of this disease who could not be admitted to mental hospitals, was under consideration.

Obituary.

SIR H. N. THOMPSON, KCMG, CB,
late AMS

MAJOR GENERAL Sir Harry Neville Thompson, KCMG, CB DSO, Army Medical Staff (ret.) died at O'borne on June 21, aged 64. He was the son of the late Rear Admiral Sir Harry Thompson, rector of Clonmilly, Down, and was educated at Trinity College, Dublin, where he obtained MB and ChB in 1883. Thirty-six years later he was conferred upon him the honorary degree of MD. He entered the army as surgeon on August 2nd 1884 and became colonel on November 17th, 1913 and major-general on December 26th, 1917. He was in the army since 1884.

His first experience of active service was in the Nile campaign in 1898 when he received the British and Egyptian medals. In South Africa he served from 1900 to 1902, taking part in the relief of Kimberley, in operations in the Orange River, in the Tlokoeng, and in the actions of Paardeberg, Poplar, Pretoria, and Diamond Hill, and in the actions at Johannesburg. He was mentioned in dispatches in the *London Gazette* of November 15th 1901, and named the Queen's medal with two clasps. In the recent great war he went out with the original expedition to Belgium, as colonel and ADMS of the 2nd Division, and, in the retreat from Mons, remaining with the advanced field hospital, was taken prisoner, and held in Germany as a prisoner of war for six months. The hardships which he then underwent had a permanent effect on his health.

After his release he served successively as ADMS of the 48th Division, as DMS of the 6th Army Corps from May 20th 1915, as DMS of the 1st Army from July 1917 and finally as DMS of the British Army of the Rhine. He was mentioned in dispatches at least five times—in the *London Gazette* of January 1st, 1916 June 15th 1916, December 24th, 1917, May 25th, 1918, and December 30th, 1918, and received the CMC in 1916, the CB in 1918, and the KCMG in 1919. He received also the French Croix de Guerre, the American Distinguished Service Medal and the Portuguese Order of St. Aviz, of which he was a Grand Officer. He held also the Coronation and Durburgh medals of 1903, and King George's Coronation medal of 1911.

We are indebted to Lieut.-General Sir William Ellis, KCB, FRCS, Director-General AMS, for the following appreciation.

The news of the death of Sir Harry Thompson will come as a great shock to the members of his old corps and will cause widespread sorrow. Throughout his service he had been one of its most outstanding and popular figures, while his gift of inspiring not only admiration, but also warm affection, earned for him an unusual number of close and lifelong friendships. The soldier never had a bitter friend, and the Royal Army Medical Corps has had few officers devoted more whole-heartedly to its interests and well-being. Sir Harry might have been regarded as expressing through his own personality the very soul of *esprit de corps* that quality so hard to define though so well understood by every soldier and, in its true significance, so misunderstood outside the army. His athletic record, his kindness of heart, and his handsome and genial presence would in themselves have ensured his popularity with his comrades but in a sense these tended to mask the sterling qualities of character which were so abundantly displayed at times when stress or emergency called for the best that was in a man. A striking personality, a gallant comrade, has left us, but he has left a memory and an example which will not readily be forgotten in the corps to which he devoted his life.

Treatment of Yaws.—Mr. Oimshy Gore (Under Secretary for the Colonies) told Colonel Day that he was not aware of any increase in the prevalence of yaws in East Africa but that prevalence was undoubtedly serious. Its cure by intramuscular injections of the East African Commission which also noted the delay in utilizing in Kenya the experience gained in Tanganyika. But the remedy had been in active use in Kenya for at least three years and he did not think any special action was necessary to make the preparation available in larger quantities.

Chinies for ex-Servicemen.—Major Tryon (Minister of Pensions) said in reply to Captain Hudson that the British Red Cross Society had intimated that it could not continue the claim for disabled men in Broad Street Holborn unless the number of pensions were increased. With the patients had to be directed of cases this was impossible and the general decline in the number to the more permanent clinics of the Ministry among others to that at Buhaga Street Millbank where the facilities for all varieties of treatment were particularly good.

Ante-natal Work.—The Minister of Health has stated in answer to questions (1) That of the areas mentioned by the Chief Medical Officer in his report for 1924 as showing excessive rates of infant mortality most as a result of the issue of a circular from the Ministry of Health were already taking steps to provide additional facilities for the ante-natal examination and institutional treatment of pregnant women. The medical officers of the Ministry paid special attention to these points on their visit to the areas concerned. (2) That under the existing National Health Insurance Act attendance at confinements was not included within the scope of medical benefit. The question of providing a maternity service under the National Insurance Acts had been brought to the notice of the Royal Commission on Health in 1924. The Council of the Southwark Borough Council did not provide the instance of by midwives for confinements but the London County Council received notice in 1924 that the aid of doctors was required in 1924 and refused it in three cases where the income of the family was above that laid down in the scale for necessitous persons. One woman general relieving officer in Southwark is principally concerned with the parents of necessitous children.

Veneral Disease.—The Minister of Health informed Mr. Bennett he was aware that Colonel L. W. Harrison of the Ministry of Health had at the Congress of the Royal Institute of Public Health at Brighton on May 29th objected to the honorary secretary of the Society for the Prevention of Veneral Disease quoting from the evidence of witnesses before Lord Trevelthins Committee on the ground that that evidence was confidential. The Ministry of Health had not received from the Trevelthins Committee a request that the evidence should be treated as confidential and Mr. Chamberlain understood that it decided not to ask for publication. In reply to Sir William Davison Mr. Chamberlain said the Government had not yet decided to allocate to the Society for the Prevention of Veneral Disease a portion of the grant for propaganda and education in the prevention and combating of veneral disease.

Ophthalmic Benefit.—Mr. Neville Chamberlain informed Mr. Bennett that the new model scheme for the provision by approved societies of ophthalmic benefit is an additional benefit contained a provision that except in the case of renewal or repair of optical appliances the applicant for the benefit must have obtained and furnished his society with a written recommendation from a medical practitioner. Representations both from bodies representing opticians and from representatives of the medical profession including ophthalmic specialists had received due consideration.

Shortage of R.A.M.C. Officers.—The Secretary for War answered Major Harvey said it was impossible to deal within the limits of a parliamentary answer with the reasons which might account for the present shortage of Royal Army Medical Corps officers or with the steps the War Office was taking to find a remedy.

Preservatives in Foods.—The Minister of Health has stated in reply to questions (1) that the form in which the regulations giving effect to the principal recommendations of the Committee on Preservatives in Foods should be finally made is under consideration. (2) The deaths reported as due to ptomaine poisoning during the five years 1920 to 1924 numbered 32, 48, 22, 21 and 16 respectively. It was not possible to state in how many of these cases the poisoning was due to the eating of tinned foods.

Bovine Tuberculosis.—Figures to show the percentage of cattle in the whole country found to be tuberculous when slaughtered are not available. At the Aldgate slaughterhouses in 1924 the percentage of all bovines found to be tuberculous was 0.45 of bulls, 4.40 of calves, 0.04 of cows, 28.0 of heifers, 3.1 and of oxen 2.0. These proportions were probably below the average for the whole country. Tuberculosis is rarely found in sheep slaughtered for food.

Votes in Brief.
In 1924 twelve deaths in England and Wales were returned by medical certificate or coroners inquest as due to insect bites. The Home Secretary states that provision is made under the regulations of the Workmen's Compensation Act whereby in any difficulty the referee can obtain a x-ray examination and that x-ray photographs are frequently arranged for by the medical referees. No representation has been made to him for any further provision.

L J McWELNIA, M D, M Ch, F R C P I,
 Profes or of Pathology and Bacteriology, University College,
 Dublin

WE announce with much regret the death, at the age of 61, of Dr L J McWeeney, Professor of Pathology and Bacteriology in University College, Dublin (National University), which took place at his home in St Stephen's Green, Dublin, after a long illness. He was a distinguished man in medical science, and his death at a comparatively early age must be regarded as a national loss.

Ldmond Joseph McWeeney was the eldest son of the late Mr T McWeeney, at one time a prominent figure in Irish journalism. In his boyhood he gave early promise of distinction in the Catholic University in the years preceding the foundation of the Royal University, subsequently he went to the College of St Beitin at St Omer. He matriculated in the Royal University in 1881, at the first examination after its foundation. In the following year he won a university scholarship in modern languages. In 1884 he obtained his B A degree with first-class honours and, as a result, was one of the first group of graduates of the Royal University in Ireland whose academic career had begun with its foundation. During his arts course he had commenced the study of medicine, and after graduating in arts he gave his undivided attention to medicine. In 1887 he passed his M B, B Ch, and B A O examinations with honours. In 1888 he went to the University of Vienna, where he studied pathology under Rokitsanski. The following year he devoted to the study of bacteriology under Koch at Berlin. On completion of his course of study under Koch, McWeeney returned to Dublin in 1890, trained as few young Irish doctors were at that time in pathology and bacteriology. This training he put at the services of his old medical school in Cecilia Street, at which so many distinguished Irish doctors received their medical education. He took his M D degree in 1891, and three years later won the first medical studentship of the Royal University.

From 1891 to the present year Professor McWeeney was at the head of the department of pathology and bacteriology at the medical school of University College. A tireless worker, he was familiar with the scientific literature of the Continental medical centres, and his contributions to medical literature were numerous. Among the public positions which he held were those of bacteriologist to the Local Government Board, Crown analyst in Ireland, pathologist to the Mater Misericordiae Hospital, and to the Coombe and the National Lying-in Hospitals. In addition to the degrees of his own university, he held the Fellowship of the Royal College of Physicians in Ireland, the D P H of the Royal College of Surgeons, the Fellowship of the Royal Academy of Medicine, and was a member of the British Medical Association for many years.

HENRY CORBY, M D, M Ch,
 Professor of Obstetrics and Gynaecology, University College,
 Cork

THE death of Professor Henry Corby, M D, which took place recently at his residence in St Patrick's Place, Cork, has removed one of the foremost members of the profession in the city of Cork.

Henry Corby was born on September 27th, 1848. He was the youngest son of the late William Corby, of Cashel, co Tipperary. He entered at an early age the Queen's College, Cork, which was then one of the three constituent colleges of the Queen's University in Ireland. His first intention was to study for law, but soon after entering the Cork College he changed his mind and entered the medical school. During his time in the medical school he attended the arts lectures and took his B A degree in due course. Having pursued a distinguished medical course he received in 1875 the degrees of M D, B Ch, B A O of the Queen's University. Almost immediately after obtaining his medical degrees, he was appointed house surgeon in the North Charnitable Infirmary, Cork, and later was appointed surgeon to the same hospital. In 1883, on the resignation of Professor Macnoughton Jones from the chair of midwifery in the medical school of the

Queen's College, Cork, Dr Corby was appointed his successor, and occupied the office until his death. Dr Corby also held the positions of consulting physician to the Cork Maternity Hospital and surgeon to the South Charnitable Infirmary, Cork. He was long a member of the British Medical Association, and represented the Munster Branch on the Irish Committee.

Professor Corby was a member of the Cork Corporation, and occupied the position of High Sheriff of the city. At the various literary and scientific societies in Cork he delivered many lectures, which were subsequently published in pamphlet form. Among these were "Experiences of a House Surgeon," "Health Homes," and "Industry and Ability." In 1881 he married Katie, daughter of Thomas Coppinger-Cronin, Kerry Hall, Cork. Of the marriage there were twelve children of whom five survive, the eldest is Dr Cecil Corby of Summerhill, co. Meath. Leo, the youngest son, practised as a dental surgeon in Cashel, co Tipperary, and lost his life in very tragic circumstances while motoring to Cork during the civil strife, he failed to hear the military challenge and was shot dead.

H GRAEME ANDERSON, M D GLAS, F R C S ENG,
 Surgical Consultant, R A F, Surgeon St Mark's Hospital

WE regret to record the sudden death, on June 28th, of Mr H Graeme Anderson, a surgeon of great ability, who had identified himself, during the war and after, with the medical and surgical aspects of aviation. While playing in a lawn tennis tournament he was seized with a heart attack and died almost at once. Only the day before he had attended, in his official capacity as consulting surgeon to the R A F, the Royal Air Force pageant at Hendon. The news of his untimely death has been received with consternation among a wide circle of colleagues and friends.

Henry Graeme Anderson was born on August 1st, 1882, the younger son of Nicol Anderson of Brailhead, Renfrewshire. After studying medicine at the University of Glasgow, at King's College, London, and at the London Hospital, he graduated M B, Ch B GLAS in 1904, obtained the diploma of F R C S Eng in 1909, and proceeded M D, with commendation for his thesis in 1919. For two years he was house surgeon, and later pathologist, to St Mark's Hospital for Cancer and Diseases of the Rectum, and he acted as clinical assistant at the Hospital for Sick Children, Great Ormond Street, and in the aural department of the London Hospital. His next posts were those of surgical registrar to the Royal National Orthopaedic Hospital, the Metropolitan Hospital, and the Cancer Hospital. On his appointment as assistant surgeon to St Mark's Hospital he began to acquire a considerable experience of rectal surgery, and in particular of the operative treatment of haemorrhoids. He published two papers on this subject in our columns before the war: the first (in 1909) gave the after-results of 300 operations, and the second (in 1913) discussed the three operations in common use at that time at St Mark's.

On the outbreak of war Graeme Anderson joined the Royal Navy as surgeon lieutenant. He was attached as surgeon to the original R N A S Expeditionary Force, and served at Antwerp and Ypres, and on the Belgian and North French coast. In 1917 he was appointed surgeon to the British Flying School at Vendome, France, and in the two following years held the corresponding post at the central R A F Hospital. He was transferred later from the Royal Navy to the Royal Air Force, with the rank of major. He was one of the small number of air medical officers who obtained a pilot's certificate at a time when this qualification was not compulsory, and he devoted much thought and research to the physical fitness of airmen, the prevention and treatment of aerial accidents, and the improvement of flying conditions. At the end of the war he was retained as surgical consultant to the R A F, and continued to give highly valued services in the treatment of aerial injuries and the selection of aviators from the surgical point of view. In January, 1918, he had contributed to the BRITISH MEDICAL JOURNAL a paper on the medical aspects of aeroplane accidents, and in March 1918,

we published a full report of a paper, read by him before the Medical Society of London, on the selection of candidates for the Air Service. In the following year appeared an excellent book on the *Medical and Surgical Aspects of Aviation*, edited and for the most part written by him when surgeon to the Royal Air Force Central Hospital, it was reviewed at some length in our issue of August 16th, 1919.

After his return to civil practice Gwynne Anderson resumed work on the staff of St Mark's Hospital, where he was promoted full surgeon, and at the Belgrave Hospital for Children, where he was senior assistant surgeon. He acted also for a time as surgical specialist to the Ministry of Pensions. With increasing experience in rectal surgery his reputation steadily grew. He contributed articles on this subject to Baughn's *System of Operative Surgery* and to the *Practitioners' Encyclopedia of Medicine and Surgery*, and was elected a member of council of the Subsection of Proctology in the Royal Society of Medicine. Last summer he contributed to our columns, jointly with Dr Cuthbert Dukes, a paper on the treatment of hemorrhoids by submucous injections of chemicals.

Gwynne Anderson leaves a widow and one daughter. At the funeral service on July 2nd, at St Columba's Church, Port Street, the Air Council was represented by Air Commodore David Munro, Medical Administrator, R.A.F., and there was a large gathering of hospital and service colleagues and personal friends.

W J J STEWART, M.D. (Ed.), D.P.H. (Cam),
Medical Superintendent, Willesden Municipal Hospital

We regret to record the death of Dr Stewart, medical superintendent of the Willesden Municipal Hospital, at the age of 57. He had been in poor health for some time, and his final illness was the result of influenza contracted early this year. His devotion to duty made him continue at work when wiser counsels should have prevailed. He had been in the service of the Willesden Council for the past twenty-two years, and during his period of office the hospital came to be regarded by the public and by the council as one of the best of the municipal institutions of Willesden. Dr Stewart spared himself in no way to make the public understand that the hospital was conducted in their interests and for their benefit, and that he and all the staff were entirely at their service.

William James Johnstone Stewart graduated in medicine at the University of Edinburgh thirty-four years ago, and proceeded M.D. in 1896 after obtaining the D.P.H. at Cambridge in 1895. He devoted his life to the study of infectious diseases and the administration of isolation hospitals, and he came to be recognized as one of the first authorities on these subjects in the country. During the war he was chosen by the War Office to take charge of the Adington Park War Hospital for soldiers suffering from infectious diseases. He built up and administered this large hospital in a manner which gave the highest satisfaction to both the military and civil authorities concerned, and well earned the gratitude of his country.

A colleague, closely associated with him in his work, writes: "Stewart's loss will be felt keenly by all his colleagues, for he was a genial man with a kindly heart, ever ready to exert himself and take any amount of trouble to help his juniors and further their interests. Dr Stewart was one of the many silent workers in the municipal service whose works are more the subject of criticism than of praise, but who nevertheless at all times and in all circumstances perform their duties with a singleness of purpose and conscientiousness which is characteristic of the official life of this country. He leaves a widow, to whom we extend our heartfelt sympathy in her sad bereavement."

Professor H. Kossatz, a well known hygienist of Heidelberg, has died at the age of 61.

Dr Burton, professor of hygiene in the Lillo Faculty of Medicine, and Dr Anderson of the Caen Medical School, have recently died.

Medico-Legal.

AN ACTION FOR NEGLIGENCE

POWELL v. MAYBURY

A special jury at the Hampshire Assizes on June 20th awarded Mr. Percy John Powell, a fancy goods dealer of Southsea, £1,000 damages against Dr. Alexander Maybury of Hampshire, for alleged improper medical treatment and negligence.

The action was tried by Mr. Justice Shearman, and counsel were for plaintiff Mr. Lyster Goddard, K.C., and Mr. W. Blake Olliver, for defendant Mr. F. B. Charles, K.C., and Mr. W. J. H. Brown.

The Pleadings

In the pleadings the plaintiff stated that from September to November 1921 he engaged the defendant to attend and treat him for neuritis in the right arm and alleged that such treatment was negligent and unskilful. On October 26th when the defendant was endeavouring to break down adhesions in the plaintiff's right arm while the plaintiff was under an anaesthetic the defendant dislocated the arm and broke off the lesser tuberosity of the humerus. The plaintiff alleged that Dr. Maybury used greater violence than was necessary or prudent and that the violence was negligent and unskilful. On November 1st the defendant performed an operation on the plaintiff while under an anaesthetic with the object of reducing the dislocation. The operation failed and the plaintiff alleged that, although the defendant continued to attend him up to the middle of November, the defendant took no further step to reduce the dislocation. As the result of the alleged negligence the plaintiff went into the Royal Portsmouth Hospital and underwent a further operation on November 23rd for the dislocation of the shoulder joint and his right arm was now two inches shorter than his left and he could not lift the arm away from the body. The defendant absolutely denied that he was guilty of the alleged negligence and unskilfulness, and said his treatment was proper and ordinary.

Plaintiff's Case

Counsel for the plaintiff said actions of this kind were serious and were brought with some reluctance because nobody liked to charge a professional man with negligence in the performance of his professional duties. But there were two sides to the question and one had to remember that they were dealing not only with the status and reputation of a professional man but also with the plaintiff, who would not bring an action of this sort without good ground and unless he had suffered severely. The defendant had been in practice for many years at Portsmouth and the plaintiff was a middle-aged man who throughout his life had been active in conducting his own business besides being a keen tennis player. During some part of his life he was troubled with pain in his shoulder which at one time was diagnosed as neuritis and also with gastric trouble. On September 17th 1921 he consulted Dr. Maybury who correctly diagnosed the gastric trouble as due to pyrosis and advised the plaintiff to have some teeth extracted. Under Dr. Maybury's advice Mr. Powell made considerable progress, and so far as the medical treatment was concerned there was no complaint. Dr. Maybury also diagnosed that the plaintiff was suffering from neuritis in the shoulder and on October 25th while under an anaesthetic there, Dr. Maybury operated to break down any adhesion which might be in the shoulder, and counsel invited the jury to say that in the course of manipulation, Dr. Maybury dislocated the plaintiff's right shoulder. It was a dislocation of some considerable extent. Counsel said that it was essential in the interests of the patient that steps should be taken to reduce the dislocation immediately. If this were left, reduction became impossible without an operation. That was what had happened in this case. Whether Dr. Maybury realized at that time that he had dislocated the plaintiff's shoulder was one of the questions the jury would have to consider. If he did not counsel then submitted he ought to have known. Something happened which caused the doctor anxiety, and that something could only have been the dislocation of the shoulder. Plaintiff was put to bed but no bandage was applied to the shoulder or to the arm. When Dr. Maybury saw the plaintiff the following evening he expressed no anxiety and did not indicate that anything upward had happened. Next morning the plaintiff found himself quite helpless in his right arm, and he could not dress himself without assistance. With Dr. Maybury's consent the plaintiff went home, where he faints and the plaintiff's daughter, a trained nurse with experience in orthopaedic cases at St. Thomas's Hospital, could not understand his collapsed state. She questioned Dr. Maybury who must at the time have had grave suspicions which he did not disclose to her. On four occasions Dr. Maybury pushed his fist under the patient's arm and applied pressure which was the recognized method adopted by surgeons for reducing an ordinary dislocation. On October 31st an x-ray photograph was taken and the plaintiff's daughter was not allowed to be present. Dr. Maybury would not allow a second opinion to be taken, but insisted on a second operation which took place in the nursing home the same two doctors being present. It was not successful, but Dr. Maybury told the plaintiff he was satisfied with the progress he was making, and that everything was going on well. Dr. Maybury refused to allow the plaintiff to see his brother, who was a doctor, but eventually the plaintiff became so dis-

satisfied that he went to Brighton to see his brother. As a result he entered Portsmouth Hospital, where Dr Smith, the house-surgeon, saw at once that his arm was dislocated, and, after an x-ray photograph was taken, an operation was performed by Mr Harold Burrows. After the time which had elapsed it was impossible to reduce the dislocation, and the arm was now shorter by two inches, which meant that the plaintiff was gravely handicapped for the rest of his life. Counsel submitted that the most skilful surgeons sometimes made mistakes, but it anything went wrong the patient expected the surgeon to tell him and take every step in his power to remedy it.

Counsel's opening was borne out by the plaintiff, but both the nursing home sister and nurse said in their evidence, that they heard nothing whatever while the arm was being manipulated.

The plaintiff's daughter in her evidence, said she told Dr Maybury that she thought her father's arm was fractured, but the reply was "No there is nothing to worry about."

Dr N R Smith said when he first saw the plaintiff's shoulder at the Royal Portsmouth Hospital it was obvious that some gross injury had been occasioned, but what it was he did not know at the time.

Mr Harold Burrows F.R.C.S., said the x-ray photograph indicated a dislocation in fact it was obvious apart from the photographs, but it was not clear how long it had been obvious. It was beyond reduction, and when he operated the humerus was dislocated and the lesser tuberosity was torn away. The tearing off of the lesser tuberosity was not recent and healing had taken place. It was not a common thing for a fracture to take place when breaking down adhesions, but he had heard of cases. It ought not to happen. After a dislocation occurred it was important to reduce it at once.

Defendant's Case

Counsel for Dr Maybury in opening, said the allegations were every bit as bad as a criminal matter. Dr Maybury had been in Portsmouth for forty years, was well known, and had had dozens and dozens of operation cases which had been successful during the whole of his career, there had never been a suggestion that he was negligent or unskilful. The accusations that he had not exercised the ordinary skill of a general practitioner were absolutely untrue. Was over an attack launched upon a doctor in the circumstances more unworthy, more ungenerous, than this attack? From the very first Dr Maybury attended the plaintiff who was not a rich man, with an assiduity and care that was altogether admirable. It was admitted that the medical treatment was perfectly good. The case was loaded with prejudice. If there were a fracture of the tuberosity it might just as well have been done in the hospital as out of it. Dr Maybury had not to exercise the highest skill, but he had to be reasonably careful and not go below the professional standard. A doctor could not guarantee not to make a mistake. He did not admit that there had been a mistake, but if there had been Dr Maybury would tell them that rightly or wrongly, his impression was that he got the shoulder back to justify the strapping, and he hoped and believed that there would be a reduction of the dislocation as soon as it was released the head of the bone slipped out of position. But for Miss Powell and the plaintiff's brother's interference the operation performed by Mr Burrows would have been performed by Dr Maybury. Counsel maintained that it was Mr Burrows's cutting which had hurtened the plaintiff's arm, any doctor would first try to reduce the dislocation by manipulation before doing what Mr Burrows did, the cutting was the last resource. Dr Maybury's only fault, if there was a fault, was that he was too hopeful and believed he had got the shoulder back so clamped it down and left it to set, but the condition of the shoulder was such that this was impossible.

Dr Maybury bore out counsel's opening statement, and Mr W H Battle and Mr J E Adams, consulting surgeon and surgeon respectively to St Thomas's Hospital, London, gave evidence in support of the defendant.

The Judge's Summing Up

Mr Justice Shearman in summing up, said it was for the jury to fix the standard of skill which they considered a patient had a right to expect from a medical man. The jury had to decide whether the defendant was guilty of negligence on October 25th. It was alleged that Dr Maybury was a bungler and was not fit to do his job that he used violence and dislocated the shoulder through negligence. It was also suggested that the anaesthesia was incomplete, but of that there was no evidence. On the other hand it was stated that such a dislocation could arise under proper and correct treatment and the jury had to be satisfied before finding in favour of the plaintiff that there was negligence in causing the dislocation. Another difficulty of the case was that the plaintiff said the doctor was negligent in that after the dislocation he did not discover it and immediately put it right. The defendant said he discovered the dislocation immediately it occurred and put it back at once, but the plaintiff said that was untrue and that the doctor did not know it. The dislocation having taken place the jury were asked to say that Dr Maybury did not know it until the x-ray photograph was taken, and it was suggested that not knowing was negligence. Was the defendant guilty of negligence as a surgeon on October 25th 1924 either in pushing the arm out or finding he had pushed it out in not pushing it back? If they took the defendant's view that he did his best and it was not negligence and that anybody might have done it, it was their duty to say so. The defendant claimed that he put the shoulder back and it slipped out afterwards, and that was the fault of the abnormal bone and not his fault.

The jury returned a verdict for the plaintiff as stated above, stay of execution being granted pending an appeal.

Universities and Colleges.

UNIVERSITY OF LONDON

THE UNIVERSITY SITE

At the meeting of the Senate on June 24th it was announced that the following correspondence had passed between H.M. Treasury and the University on the subject of the Bloomsbury site.

Treasury Chambers
3rd June, 1925

Sir,

I have had before the Lords Commissioners of His Majesty's Treasury Sir Cooper Perry's letter of the 13th ulto stating that in connexion with proposals by the Delegacy and the Council of King's College for an appeal to the public for funds for new construction or endowments the Co-ordination and Developments Committee of London University desire to be informed of the answers to certain questions addressed to their Lordships in Sir Cooper Perry's letter of the 18th December last. My Lords regret that a reply to the last named letter has been delayed.

I am now to inform you (1) that the Lords Commissioners of His Majesty's Treasury are not able to hold out any hope that Parliament could be asked to contribute a larger sum than £370,000 building the Strand in the event of King's College and the Strand site reverting to the Crown.

(2) On the assumption that King's College would for their part be unwilling to move to the Bloomsbury site or unable to do so on these terms, my Lords apprehend that the University may desire to reconsider the policy of transferring their central buildings to Bloomsbury, and if the University can suggest any practicable alternative for an increase without undue cost of the accommodation for their central offices, my Lords would be prepared to consider it.

(3) My Lords are not without hope that it might be possible to make arrangements with the vendors of the Bloomsbury site whereby at least a part of it might be occupied on terms for other University purposes, but this might depend on the course of negotiations which have not been initiated.

R S MEIKLEJOHN

The Principal Officer,
London University

University of London
South Kensington S.W. 7,
24th June, 1925

Sir,

I am desirous to say in reply to your letter of the 3rd June that as the Lords Commissioners of H.M. Treasury have already been informed, the Senate passed a resolution in November, 1923 that in their opinion the removal and reinstatement of the secular and theological Departments of King's College on a scale adequate in the opinion of the Senate to present needs and future requirements should be effected without expense to the University or the Council of King's College in return for the surrender to the Government of the present site and buildings in the Strand. As it is certain that the expense of rebuilding King's College on the Bloomsbury site on the scale contemplated in the above resolution would far exceed the sum of £370,000 and as the Lords Commissioners of H.M. Treasury are not able to hold out any hope that Parliament could be asked to contribute a larger sum than £370,000 a reversal of value of the site and buildings of King's College in the event of reverting to the Strand in the event of themselves compelled to decline the offer contained in Mr Fisher's letter of 7th April 1920 conditionally accepted by the Senate on October 20th, 1920. Amongst the conditions laid down by the Senate was

(5) That the terms of the removal of King's College from the Strand to the Bloomsbury site shall be a matter of subsequent negotiation between His Majesty's Government, the Council of King's College and the Senate of the University, and that an agreement shall be concluded between the said parties.

It is obvious that this condition cannot now be fulfilled.

The important questions raised in paragraphs (2) and (3) of your letter will demand the anxious consideration of the Senate after reference to the relevant Councils and Committees, and to other bodies which may be interested.

The Senate note with satisfaction that the Lords Commissioners of H.M. Treasury recognize the need for increased accommodation for the central offices of the University.

E C PERRY
Principal Officer

The Secretary,
H.M. Treasury

Vice-Chancellor

Professor E. A. Gardner Litt.D. has been re-elected Vice-Chancellor for the year 1925-26.

Emeritus Professor

The title of Emeritus Professor of Hygiene and Public Health in the University has been conferred on Sir William J. R. Simpson, C.M.G. M.D., F.R.C.P. as from the end of the present session on his retirement from King's College after twenty-seven years' service on the closing of the Department of Bacteriology and Public Health.

THE Fellowship of Medicine announces that on July 9th Mr G Grey Turner will lecture on "Gall stone disease—a pit fall for the practitioner," at 5.30 p.m., in the West Lecture Hall at 1 Wimpole Street, W. The Prince of Wales's General Hospital (North East London Post Graduate College, Tottenham, N) will hold a vacation course in medicine, surgery, and the specialties from August 4th to 15th. Beginning on the same date, the All Saints' Hospital will give a month's special course in diseases of the urinary system. From August 24th to September 5th the Queen Mary's Hospital, Stratford, has arranged an intensive course in medicine, surgery, and the special departments. The fee for both intensive courses is £3 3s each, or £2 2s for either week, and for the special course in urology £5 5s. Copies of the syllabus of each, together with the Fellowship programme of the general course of instruction available under its scheme, may be obtained from the Secretary at No 1, Wimpole Street, W 1.

A COURSE of lectures and practical instruction for the diploma in psychological medicine of the Universities of London, Cambridge, Durham, etc., will commence at the Bethlem Hospital, Lambeth Road, S.E. 1, on September 14th. Full particulars can be obtained on application to the Medical Superintendent.

THE Midland Branch of the Society of Medical Officers of Health, Birmingham, proposes to commemorate the knight hood conferred on the medical officer of health, Birmingham, by entertaining Sir John and Lady Robertson at a complimentary dinner at the Queen's Hotel, Birmingham, on Friday, July 10th, at 7 p.m. All members of the society are invited. The cost of the dinner will be 10s. 6d. without wine. This amount should be sent to the honorary branch treasurer, Dr. T. Ridley Bailey, at the Health Offices, Fenn Hall, Wolverhampton.

THE managers of the Pleasant Drivon Studentship in Mental Pathology announce that they have made no award this year.

THE annual general meeting of the Council of the Association of Infant Welfare and Maternity Centres will be held at Carnegie House, 117, Piccadilly, W. 1, on Tuesday, July 7th, at 3.30 p.m. The subject for discussion is heliotherapy, with Dr. Eric Pritchard in the chair. The speakers will be Professor Leonard Hill, Dr. G. I. Stehling, Dr. C. W. Sileby, Dr. Stella Churchill, and Dr. Percy Hall. Admission is free without ticket.

At the annual prizegiving of the London (Royal Free Hospital) School of Medicine for Women, on June 25th, the Dean, Dame Louisa Aldrich Blake, announced that Lord Riddell, president of the hospital, had provided for two fellowships for research in maternity and gynaecology at the Royal Free Hospital, and that Mr. Alfred Langton, chairman of the hospital, had endowed another fellowship for research in infant feeding. Dr. Mary Thomas stated that in a few months it was proposed to institute private rooms for paying patients at the Royal Free Hospital.

THE new Watford and District Peace Memorial Hospital, erected at a cost of over £65,000, was opened by H.R.H. Princess Mary, Viscountess Lascelles, on June 24th. The Bishop of St. Albans conducted the dedication service, after which Princess Mary opened the hospital door with a gold key.

THE new wards and other additions made to the Tilbury Seamen's Hospital were opened on June 24th by Viscountess Inesbape. The Bishop of Colchester having dedicated the new buildings, the company inspected the hospital's new features, including a wing for nurses.

MRS. ELLA ROWCROFT of Torquay announced on June 25th her intention of defraying the whole cost of the erection of the new Torbay Hospital at Torquay. Mrs. Rowcroft and her sister, Miss Wills, have given £123,000 towards the new hospital, which will be begun almost immediately.

MESSRS. MAY AND BAKER, LTD., of Battersea, S.W. 11, have issued a catalogue of their pharmaceutical preparations and of vaccines for the treatment of gonorrhoea and its complications (prepared in the pathological laboratory of the London Lock Hospital). Tables of weights and volumes and of percentage solution equivalents are provided.

WE have received the first number of *La Pediatria, Archivio di Patologia e Clinica Pediatrica*, which is being issued under the editorship of Professors R. Jewmura of Naples and G. Caronia of Rome as a supplement to the fortnightly pediatric journal of the same name, the two journals being now respectively called *Archivio La Pediatria* and *Rivista La Pediatria*. The object of this new journal, which will appear at irregular intervals, is to publish works whose size and character preclude publication in existing journals except at great expense to the author. The present issue contains articles by Drs. G. Cristina and G. Caronia on the etiology of scarlet fever, accompanied by illustrations of the micro-organisms which they claim to be the cause of scarlet fever, by Dr. D. Caffarella on the plurality of the antigens in the Wassermann reaction in congenital syphilis, and by Dr. M. Gerbasi on the variability of the strains of the typhoid bacillus. The price is 20 lire.

THE London School of Hygiene and Tropical Medicine, Endleigh Gardens, N.W. 1, invites applications for four research studentships, each of the value of £250 per annum. Applications must be sent to the Secretary by August 31st. Particulars will be found in our advertisement pages.

THE following promotions in and appointments to the Order of the Hospital of St. John of Jerusalem in England are announced—As *Knights of Grace*: Lieut. Colonel F. S. Lambert, R.A.M.C. (T); Major General Sir Samuel Guise Moors, K.C.B., C.M.G., D.I.; J. J. Waldo, Captain W. T. Wood, R.A.M.C.; Major Arnold W. Izard, M.D. As *Fringes*: Lieut. Colonel J. C. Strathearn, O.B.E., D.I.; W. C. Rigby, Dr. John Rodley, and Dr. W. H. Curse.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to *The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W.C. 1*.

ORIGINAL ARTICLES and LITTEPS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C. 1 on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are: *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the *British Medical Journal*, Astology Westcott, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc.) *Articulate Westcott* London.

MEDICAL SECRETARY, *Medicera Westcott* London.

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus Dublin* telephone 4737 Dublin) and of the Scottish Office 6 Drumsheugh Gardens, Edinburgh (telegrams *Associate, Edinburgh* telephone 4361 Central).

QUERIES AND ANSWERS

TREATMENT OF DISSEMINATED SCLEROSIS

J. R. writes to inquire about intravenous injections in the treatment of disseminated sclerosis.

The intravenous injections referred to were probably with one of the salvarsan compounds—for example sodium silver salvarsan. This treatment is founded on the belief now widely held that disseminated sclerosis is an infective disease, and on the fact that certain observers have found spirochaetes in the nervous tissues after death from this disease. It is certain that this organism is not the spirochaete of syphilis and that syphilis is not the cause of disseminated sclerosis, nevertheless treatment by salvarsan and mercury on the same lines as for syphilis is probably the best treatment we have for disseminated sclerosis. In a disease which has a marked natural tendency to remission it is extremely difficult to assess the value of any mode of treatment but the results are quite sufficiently encouraging to justify the continued use of this method if the cases are recognized at a reasonably early stage. In disseminated sclerosis as in so many diseases intravenous injections of protein—for example typhoid vaccine—have also been used either alone or in addition to salvarsan treatment.

STUDY IN OPHTHALMOLOGY

'OPHTHALMIC' who is a graduate of medicine at present practising in one of the Dominions wishes to know what course he should pursue with a view to obtaining post-graduate study in eye work, towards which he has a strong inclination. He asks what are the facilities in London and Paris and what diploma might be obtained.

There are ample facilities for the study of ophthalmology both in London and in Paris. There is also a choice of English diplomas in ophthalmology. To name the two best known there is the diploma offered by the University of Oxford and that of the Royal College of Surgeons of England. A graduate who obtains either of these diplomas secures the full mail of high attainment in eye work. If our correspondent proposes to undertake the training necessary for the attainment of either of these diplomas his work will be mapped out by the course prescribed by the bodies issuing the diplomas. These he can obtain by inquiry from the Secretary of the Medical School, Oxford University or from the Secretary of the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C. 2. The courses are very similar and require attendance on prescribed courses of study practical work and clinical work. The course is strenuous and means real work. One year's study in a recognized hospital is necessary before a candidate may enter for the examination, and in the case of the Oxford diploma two months of this year must be spent at Oxford. If he is well grounded in general medicine and has a good foundation in the physical sciences, our correspondent should have no difficulty in carrying out the prescribed course of study in the time allotted. If his ambition

do not run to the course prescribed for candidates for the diplomas, he might take up post graduate study of eye diseases and a course of refraction work at any of the British or Parisian hospitals which do post graduate work. The British hospitals are cited in the Educational Number of the BRITISH MEDICAL JOURNAL, published each year early in September, and brief notices of these same hospitals will be found in the Medical Directory under the sections devoted to hospitals and also in the advertisement pages.

POWER OF ENTRY BY LOCAL AUTHORITY

"R P" writes: Has an Inspector of nuisances employed by a rural district council the right of authority to demand admission into the private residence of an invalid in order to inspect the house and take measurement of rooms etc?

* * Section 102 of the Public Health Act, 1875, relating to nuisances, deals with the power of entry of the local authority. This Section states *inter alia*: "If admission to premises for any of the purposes of this Section is refused any Justice on complaint thereof on oath by any officer of the Local Authority (made after reasonable notice in writing of the intention to make the same has been given to the person having custody of the premises) may by order under his hand require the person having custody of the premises to admit the Local Authority or their Officer." Section 103 of the Public Health Act, 1875 states: "Any person who refuses to obey an order of a Justice for admission of the Local Authority or any of their Officers on any premises shall be liable to a penalty not exceeding £5." Having regard to these sections it is likely that the magistrates would grant an order to inspect the house, but unless it was represented to them that inspection was urgently required on account of some nuisance dangerous or injurious to health they would be unlikely to grant the order to the detriment of the sick person occupying the house. The power of the justice in this matter is discretionary.

INSULIN IN CANCER

"A" asks for notes of any experience of the use of insulin in inoperable carcinoma. He would welcome suggestions as to dose, the intervals between doses, and the tests necessary.

INCOME TAX

Principles of Assessment

"A M H" has purchased a practice having previously resided outside the United Kingdom, and seeks general advice.

* * Our correspondent should bear in mind that income tax is payable on earnings, whether realized in cash or not and that the amount of the net cash receipts can be substituted for the profits, computed on the value of the fees booked only when the circumstances justify the assumption that there will not be a substantial difference between these figures. He is liable to be assessed on the basis of the past three years' profits of the practice he has purchased, but if at the end of the year he can show that for some specific cause—for example the change of proprietorship—the profits have fallen short of the amount assessed he can claim an adjustment accordingly. There are several guides to the income tax regulations, that published by Nelsons at 2s 6d, or thereabouts, is a very useful one at the price.

Purchase Money

"A E S" owes his late partner a part of the purchase price of his practice and pays interest thereon, the Inspector of taxes insists on deducting this amount in calculating the income on which the earned allowance is due.

* * The point has not been settled by judicial authority but we should not regard "A E S's" prospects of appeal as good. In substance, "A E S" is assessed in respect of two incomes—his own earned income and the interest which he pays, and which is, in essence, income of his late partner. On this latter income he accounts for the tax to the Revenue and recoups himself for the amount so paid by deducting it from the interest when he pays his late partner. But that interest is investment income to the recipient and we fear the courts would not uphold a claim to regard it as earned income of the payer.

Three Years' Average

"NFLHL's" income from professional earnings has been falling and consequently his average assessment is higher than his earnings for the year of assessment. Has he any remedy?

* * The answer is in the negative. The special provision which authorized an adjustment was repealed after the war, and the average is now open to review only in special circumstances—for example, after a change in the proprietorship of the practice, or if an actual loss on working is incurred.

LETTERS NOTES ETC

Punch's contribution to the celebration of the railway centenary takes the form of a special supplement to the issue of July 1st giving a full account of his activities as a railway hero's critic, prophet and humorous commentator from 1841 down to the present day.

THE MEDICAL WITNESS

DR ABRAHAM ARABIAN (London, W.) writes: I have no doubt that the majority of your readers must have shared my experience of having been twitted by members of the legal profession with our traditional inability to say old unnecessarily long technical terms. And I have no doubt that they will all have shared my experience of having been confronted with that choice piece of pathological hyperbole translated by the learned judge in the case as "just a hunch." I can remember hearing it to the court of at least half a dozen occasions in the past twenty years whenever an article on the subject appears one looks for it with perfect confidence and now I see that even an eminent legal counsel selects this venerable example in his exhortation to medical witnesses to use "simple language." I confess I have always regarded the doctor who was originally responsible for this piece of evidence as a lineal descendant of Mrs Harris the choice perfection of the composition smells too much of the lamp. But it is possible that it really issued from the lips of a colleague whose accuracy and fluency were indeed to be envied if we deplored his lamentable lack of a sense of proportion. And it is equally possible that one of your readers as inquisitive and as sceptical as I, but more enterprising, can supply chapter and verse. But in any case I feel it is about time that we were entitled to receive during the course of instruction when we are to be stigmatised for our inability to express ourselves in "plain English," another example of what should not be said or which is quite as convincing and, if I may say so, much more probable.

POSTURE TO AID DELIVERY OF DETACHED PLACENTA

DR CHARLES J. HILL (Aitken, (Aitken) near Rotherham) writes: According to Shears (*Obstetric*), "Delivery from the vagina is favoured by the lateral position. If a patient receives a vaginal douche in the dorsal position the solution is retained but if she turns upon her side the solution runs freely from the vagina. A patient delivered herself lying on her back. Thirty minutes later pressure from above failed to deliver the placenta although I felt sure it was in the vagina. The midwife suggested that the patient should turn on her side. This she did and with slight pressure the placenta was on the bed. The pelvis was roomy, the placenta small. In the dorsal position the small placenta lay in the hollow of the sacrum, posterior to the hue of pressure applied. By changing the posture of the patient the placenta was brought into the line of pressure and so was easily delivered."

GALL STONES IN ADOLESCENTS

"EVE, M.B." writes: May I add yet another to the already long people instance of the last few months? A schoolgirl between 13 and 14 years of age when she had suffered for a year or two for symptoms so that the trouble must have been present at an even earlier date. Symptoms occurred periodically, and included jaundice pain referred to the epigastrium, and a rise of temperature—sometimes to 104° F. As my condition did not respond to medical treatment and the outlook seemed desperate, a surgeon was called in. He operated as I was recovering from an exceptionally severe bout and found an enlarged gall bladder quite empty, a widely dilated common duct and a liver showing signs of impeded biliary outflow. Nature had evidently just effected a cure by the passage of a large stone. Drainage was instituted and I made an uneventful recovery, and have never had a recurrence of the familiar symptoms. I or obvious reasons I prefer anonymity, but enclose my card.

A WARNING

THE Registrar of the General Medical Council writes: I understand that advertisements for an assistant or a locum tenens have been answered by Mr K R G Shaw. Practitioners should be warned that before engaging him, it is desirable that inquiry as to his registration should be made at the office of the General Medical Council, 44, Hallam Street, Portland Place, London, W. 1.

CORRECTION

We are asked to make the following corrections in the paper on the estimation of the cardiac output as a measure of its efficiency by Dr T. Stacey Wilson, published in the JOURNAL of June 27th (p. 1167). Column 1, line 14 from foot for "a certain amount of definite elasticity" read "a certain definite amount of elasticity." Column 2, line 14 from top for "the middle line of the costal arch" read "the middle line on to the costal arch."

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 32, 34, 35, 38 and 39 of our advertisement columns and advertisements as to partnerships, assistantships and locum tenencies at pages 36 and 37.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 12.

The Mackenzie Davidson Memorial Lecture OF THE RELATIONSHIP OF RADIOLOGY AND SURGERY.

DELIVERED BEFORE THE INTERNATIONAL CONGRESS
OF RADIOLOGY, JULY 3RD, 1925,

BY

SIR BERKLEY MOYNIHAN, Bt, F.R.C.S.,
Leeds

It must, I feel sure, be difficult for the younger generation of physicians and surgeons fully to realize the magnitude and the high value of the help that is now given to us by the work of the radiologist. Each generation inherits the work of its forerunners, and it requires an effort of imagination denied to most of us to picture the conditions of earlier days in which many of our present resources were still undeveloped. None of us, I think, quite appreciated the difficulties against which Lister had to contend in his early investigations until we were suddenly confronted with the nauseating and startling horrors of those heavily infected wounds with which we had to deal in the first few months of the great war. And the lessons we learnt then increased, if that were possible, both the admiration we all felt for the toilsome and honest work that Lister did, and our gratitude for the imperishable heritage which he bequeathed to us.

So it is also with radiology. It requires a considerable effort of memory, and some skill in reconstruction, to recall for ourselves the days when only the note given by a sound in the bladder as it impinged against a stone made certain the diagnosis of calculus. The word "certain" is too emphatic, for I can still vividly remember Marcus Beck telling us in his ward at University College Hospital of the errors in diagnosis that might then arise when the sound struck the spine of the ischium and produced a muffled note, or when a trilet on the watch chain of the surgeon twinkled at the moment the instrument was rotated in the bladder. Nor can I easily forget the infrequency with which an exploratory operation upon the kidney revealed the presence of the stone whose existence had been confidently predicted, nor the uncertainty and ill success which attended the search for a calculus in the ureter. The change from those days, with the hesitation, the guesswork, the bitter and humiliating disappointments, to these days of confidence and precision is almost immeasurable, and it is to the devoted and skilful workers in the fields of radiology that we are grateful for the transformation. It is natural and fitting that this day should be held as a day of remembrance for one of the greatest of the pioneers—Mackenzie Davidson. It will, perhaps be appropriate if, in my role of a physician doomed to the practice of surgery, I endeavour to show, more particularly in connexion with abdominal diseases, in what degree we have taken advantage of the new methods of diagnosis and of treatment which radiology has afforded us.

DIAGNOSIS

Let me begin with the pharynx and oesophagus, though in evening's entertainment might not unprofitably be devoted to a discussion of the value of radiology in connexion with the disorders, real or assumed, of the hidden portions of the teeth. It is true that diverticula of the pharynx were known long before the days of radiology. The first case was related in a letter from Mr Ludlow, a surgeon of Bristol, to Dr William Hunter of Glasgow and is recorded on page 85 in volume 3 of the *Medical Observations and Enquiries* of 1767. Ludlow speaks of a "preternatural bag" in the pharynx. The figures he gives are exquisite, and are unsurpassed for beauty and accuracy by any later illustrations. The specimen is in the Hunterian Museum at Glasgow to this day and a recent drawing of it shows that it has changed very little in the last 150 years.

The diagnosis of the condition in its fully developed state

is not difficult. Radiology not only makes the diagnosis quite certain, but it gives a quality of precision that could not otherwise be obtained. We learn not only that the preternatural bag is there, but we know where it lies, how large it is, what attachments it has made, and all details that may be helpful to us at the time of operation.

Of diverticula of the oesophagus we knew nothing before the days of x-ray examinations except that which was learnt from *post mortem* examinations. These little *wayside* turrets are not often of clinical importance. When filled with food they press upon and distort the tube from which they spring, and cause an uneasy suspicion as to the presence of cancer, a suspicion that only time allays.

Oesophagus

Of the condition known as *cardiospasm* we could, of course, know nothing accurately apart from the examination made by the radiologist. It is true that our museums contain many specimens of "idiopathic dilatation of the oesophagus," but the recognition of this deformity, the knowledge of the size, position, extent, and occasions of emptying the pouch, the extent of the tube involved, and the position of the hiatus, we learn only from the screen examinations. In the first case I saw after I had just learnt of the disease from Professor Milneuz we had "washed the stomach out" many times and removed from it large quantities of fermenting, offensive, and disgusting food that had been long retained. When this little operation was repeated under the control of the x-ray we saw with amazement that the tube never entered the stomach, but lay coiled within the immense cavity formed by dilatation of the oesophagus. We failed completely to pass any bougie into the stomach though careful and repeated attempts were made. A duck-shot tied on to the end of a long piece of silk at last was seen on the screen to enter the stomach and to pass along the intestine until it emerged at the anus. When all the length of silk was entangled in the intestines and formed there a fixed point, I threaded bougies over the strand hanging from the mouth and so guided them safely into the stomach. The obstruction was fully dilated, and the patient taught to pass bougies. When she was expert the silk was cut at the mouth and at the anus, and a week later the whole length of it was vomited. Since those early days I have treated many patients, and though examinations with the oesophagoscope are made, we still rely chiefly upon the radiologist for the information which directs our treatment. There is no doubt that most of these cases were formerly regarded as malignant, and gastrectomy was done for them. A patient in the Leeds Infirmary was seen by me twenty years after this operation had been performed by Mr Ward, on the supposition that a carcinomatous growth obstructed the gullet. An x-ray examination showed the typical appearance of this disease.

The differentiation between "cardiospasm" and carcinoma now presents no difficulties, for the appearance of the oesophagus filled with an opaque medium is quite characteristic in both diseases. The large size of the oesophagus, its tolerance to food, the vigour of the peristaltic waves, which do not move the meal forward, the rounded, blunt end of the shadow which reaches to the diaphragm in cases of cardiospasm contrast as sharply as possible with the slight distension of the oesophagus, the intolerance to food, the incompleteness of the obstruction, and the narrow tapering of a shadow which is very rarely exactly on a level with the diaphragm, in cases of carcinoma.

Diaphragmatic hernia is a rare disease. Its recognition without the aid of radiology is excessively difficult or perhaps impossible. It so happens that I have had four cases in my charge—two in the time before we used the x-rays and two since. Neither of the first two was recognized until the abdomen was opened, and both were discovered with a shock of surprise. The latter two had been recognized by the radiologist, one was on the left side as most cases are, in the other the sac lay in the right side of the chest, and its contents—the stomach and the transverse colon—were easily recognized in the radiograph. I know of only one other similar case, it was operated upon by Sir Hugh Rigby.

Ulcer of the Stomach

In connection with gastric disease it is hardly too much to say that we owe almost everything to the radiologist. As we look back upon the history of gastric ulcer in respect of its symptoms, its diagnosis, and its treatment, we must now realize that before the radiologist came to the rescue there was little that could meet with our confident acceptance. I do not doubt that more errors have been made in the diagnosis of gastric ulcer than of any other disorder. Its symptoms are mimicked with so much accuracy by other diseases that it is not only the unwary who are deceived. The radiologist has put all this right, or nearly right, and has, I think, explained the cause of the so remarkable plianism by those other diseases which arouse gastric symptoms. It is, however, not only diagnosis that has been at fault, but the treatment that has been based upon it. How can we explain the devotion of physicians to the alkali treatment of gastric ulcer except on the assumption that the diagnosis upon which such methods first were founded were erroneous? For in about 80 per cent of the proved cases of gastric ulcer the free hydrochloric acid content of the gastric juice is either normal or below normal or absent. And the surgeon is far from guiltless in the matter. He has too often been content to accept the diagnosis of "gastric ulcer," and, being, as which, unhappily, he has been led to believe is a principle for all gastric disorders and a swift and certain cure for gastric ulcer. The accuracy with which a competent radiologist, given time, can make a diagnosis of chronic gastric ulcer which the operation will confirm must in time lead to the abolition of these foolish practices by us all, and a radiology will prove the most effective remedial agency for so much of the literature and practice of days that are not yet past. May I urge once again that, until our knowledge is clarified and our practice established in reason, no diagnosis of gastric ulcer based upon clinical evidence alone be accepted as a warrant for treatment? A chronic gastric ulcer, unlike the Emperor's new clothes, is a real thing. It is to be seen, and during operation can be handled, exposed, and demonstrated. If it is there at all it is there for all to see. No gifts of vision are conferred upon the surgeon which are denied to the onlooker. If the surgeon says an ulcer is there, my competent witness can test the truth of his statement. And the accuracy of the radiologist in the diagnosis of this disease nearly approaches that of the surgeon who inspects and handles the stomach. The radiological diagnosis of gastric ulcer is not, however, constant in its accuracy. The greatest difficulties are met with when the ulcers are small, lie on the lesser curvature, are close to the cardiac orifice, and veer towards the posterior surface. The sheltered position of the part of the stomach which harbours them, the overlying liver, the barrier made by the wall of the thorax, and the impossibility of direct palpation of the stomach here, all are hindrances to the exact methods applicable to the exposed gastric area. All these difficulties are, however, in some degree surmounted if the patient is carefully watched as it enters the stomach, and if convergence of the folds of the gastric mucosa to a definite point is observed. There are times when an ulcer may be demonstrated if the filled stomach is pressed down from the epigastrium by a pad of wool, more and more increased in size, the stomach is thus rotated a little on its long axis, and an oblique or transversal view may then disclose an ulcer either. The numerous errors in diagnosis are, however, so few that the accuracy of the diagnosis made with its help is confirmed. If the diagnosis of gastric ulcer is made by no matter whom, let us agree that it is not to be retied upon by the therapist with drugs or weapons unless the radiologist confirms it. It is admittedly true that this expert may sometimes fail to see an ulcer which is undoubtedly present, especially if he is hurried in his examination by the impetuosity of the physician or the impatience of the sufferer himself. But, given a good chance his errors will be few, far fewer than those of any other investigator. And it must be conceded by us all that the value of any treatment

—dietetic, medicinal, or operative—cannot be gauged unless we know the precise condition for which that treatment has been prescribed. At present, with the best will in the world, I am unable to learn anything which satisfies my intelligence as to the worth of any of the methods of medical treatment in cases of gastric ulcer. And I am not often without the opportunity of seeing lamentable examples of mischievous and needless surgery practiced upon those who were unmistakably arranged as the victims of gastric ulcer in need of surgery. In all parts of the world operations are being practiced by those whose natural gifts may perhaps warrant their ambitions to be surgeons but whose apprenticeship to the most superb and most difficult of all the arts has not been served with that devotion and surrender which alone equip a man for this office. I am amazed at the ready acceptance by patients of the eager ministrations of incompetent operators, when adequate skill and experience are at their command. The frequency of secondary operations when the first, being needless, yet produced effects that must now be undone, and of skilful operations for carcinoma, say of the breast which invite a quick new growth of carcinoma cells distributed over the carcass, wound, are a reproach to surgical work.

I think that the radiologist has done much to explain the reasons for the so frequent inaccuracy of the diagnosis of gastric ulcer. When we inquire as to the conditions which cause the symptoms of this disease, we who deal with the living are quick to admit that it is not only the presence of an open ulcer with its crater of varying depths, that is the responsible and immediate agent, for it is a very common experience to find an open ulcer when the symptoms are in temporary abeyance, the patient enjoying one of the "interludes" so characteristic of the disease. I believe that a state of active increase of the ulcer is essential to the production of symptoms when activity dies down and the ulcer makes its endeavor to heal all is quiet. The enlarging ulcer sets up a spasm in the stomach—the "miserere" of the radiologist. The "notch" on the greater curvature, opposite, or about exactly opposite, the "miserere" on the lesser curvature, is sometimes so deep that it seems to cleave the stomach into two parts. Watched attentively for as long a period as is safe, and examined from time to time, it appears unchanged. The conclusion at first was irresistible that an hour glass stomach existed. Yet when an operation was performed the spasm had vanished. The cause of the symptoms of an ulcer seems clearly to be in this spasm. The pain is doubtless due, in part, to the distension of the zone lying on the cardiac side of this spasm.

The occurrence of spasm is not, however, restricted to cases of gastric ulcer. There is a reflex spasm which in many of its qualities so closely resembles the direct spasm that in haste a false conclusion as to the presence of an ulcer may be drawn. The reflex spasm, even when it is as deep as the direct spasm, is rarely so constant, or so immobile. It is apt to be shallow, fugitive, changing from one part of the stomach to another, and it creeps part persuading one of conditions so diverse as cholecystitis, tuberculous disease of the intestine or even chronic appendicitis, and certain conditions of the central nervous system. No gastric ulcer, of course, exists without infection, infection may be present, too, in the pyloric part of the stomach when its primary source lies elsewhere. It is long since I described the "pyloric blush" of chronic appendicitis, and Bartholomew, these two conditions, spasm and infection, are present both in the true and in the apparent disease of the stomach, there is little wonder that the symptoms aroused by them should often lead even the alert and earnest diagnostician astray. The only competent authority to distinguish between operation between the spurious and the true is the radiologist, and, as I have before ventured to claim, his work has pride of place among the methods of diagnosis in all forms of gastric disease.

It is not only in the diagnosis of gastric ulcer that our resources have been so greatly augmented, but in the recognition of its occasional complications. Many years ago I laboured hard to discover, and in several papers elaborately described, the various signs which permitted the hopeful recognition of an hour-glass stomach. The signs

were many, the labour to elicit them protracted, the judgement difficult and not free from faults. Now the radiologist will tell us every detail that is relevant, not only is the diagnosis indisputable, but the site of the constriction, the size of the two complements of the stomach, the speed with which one or other will empty, the degree of adhesion if any—all, and even more than these, are stated with unequivocal accuracy.

Cancer of the Stomach

We shall all, I do not doubt, be prepared to concede our inability to diagnose cases of carcinoma of the stomach in an early stage. Of gastric carcinoma there are, speaking roughly, two great groups. In the one the patient has suffered for years at intervals from mild or severe forms of gastric discomfort. Finally, one attack, at first very like all the others, proves rebellious. Relief is not given by the remedies which hitherto have proved so easily successful. At the operation an ulcer, transformed in part to carcinoma, is found. In the second group are the cases I refer to as 'the bolt from the blue type'. The patient has perhaps been notorious for vigorous gastric health, he scorns the suggestion that he may perhaps have been a little dyspeptic. His denial of former ill health is disdainful to the point of arrogance. Suddenly he becomes ill, and perhaps the illness is ushered in by hæmatemesis of great severity. He loses zest for many things—food, his former activities of work or play, he loses weight, becomes anæmic, and when he is examined a lump is felt in the epigastrium. It is a melancholy but indisputable truth that, despite the activities of a small body of surgeons in this country, carcinoma of the stomach is almost always an incurable and fatal disorder. I should doubt if there are a hundred patients in the whole country who are alive and well five years after operation for the second type of carcinoma to which I have just referred. The reason for this lamentable condition of affairs lies chiefly in our incapacity, by any clinical means, to make a diagnosis in the early stage. As a profession we are not, however, blameless. We have not the courage of our experience. For when a patient over 45 begins with these insidious failures of health our tendency is to procrastinate, when we should not delay a moment. Lives are lost in part through ignorance, in part through timidity. The radiologist is now our strength. He is able, given time, to make a diagnosis of filling defects, to recognize interrupted waves of motion, of a break in peristalsis on the affected curvature, whilst the movement on the normal curvature is unchecked, of deflections of the current of the opaque meal, long before we could be in the least degree confident, by any other means at our command, of the presence of a growth. To ensure a success in treatment greater than that most meagre form we now command, two changes are essential. All patients about whom we have a doubt should be sent forthwith to the radiologist, and the x-ray examination should not be hurried.

Diverticula

What should we know of diverticula of the duodenum but for the radiologist? I have carefully searched the literature of this subject, and though the condition was first described in 1710 by Chomel, no case had been diagnosed during the lifetime of a patient before 1912. Yet J. T. Case, in a study of 6,847 consecutive patients upon whom a radiological examination of the stomach and duodenum was made, found no fewer than 85 cases of diverticulosis. Not many of the patients who possess these little wayside tracks from the duodenum suffer from them; their removal is therefore rarely necessary. But regard should be paid to them in all operations in which a diagnosis of duodenal ulcer, or of cholelithiasis, is not supported by the conditions disclosed at an operation, for the retention of foodstuffs in these cavities, or its fermentation, may cause symptoms which are apt to be ascribed to other lesions, and when these are not found on inspection the operation may, in ignorance of this condition, be abandoned as a failure.

Of diverticula of the jejunum occurring during life nothing could be known apart from their demonstration by x-ray examination. The cases are few in number, and the little pouches do not often cause much harm. This is all

to the good, for when present they are apt to affect so great a length of intestine as to make removal of the affected segment a matter of difficulty, or even impossible. The best example that has fallen within my knowledge occurred in the practice of my colleague Mr. Brithwaite, the radiological examination and the diagnosis being made by Dr. Rowden.

Colon

The subject of radiology in relation to diseases of the colon has so recently been discussed in London that I need say little concerning it to day. When I operated upon the first case recognized as diverticulitis in this country on April 2nd, 1906, so slight was our knowledge of the disease that a diagnosis during the life of the patient had never been made. Many of the specimens on our museum shelves bearing the label "carcinoma" were examples of the massive inflammatory thickening round these little crypts, and the fact that the majority of the fistulous tracks from the colon to the bladder were not due to carcinoma was generally unrecognized. The diagnosis of diverticulosis is now made with complete confidence by the radiologist, and by comparison of one radiograph with another taken some months later we are able to judge of the progress of the disease and to come to a decision as to whether operative treatment is likely to be necessary.

I have a number of patients suffering from this disease who are kept in good health, and are sheltered from the attentions of the surgeon, by medical treatment. This ensures a daily emptying of the intestine, and includes an orgy of aperients on the Saturday afternoons and Sundays which are given over, religiously, to the observance of the ritual of free and frequent evacuation. I find that operative treatment in the chronic form of this disease is rarely necessary.

The diagnosis of carcinoma of the large intestine may present such difficulties to the radiologist that great care is needed to avoid error. The opaque meal and the opaque enema both have their uses, but I find far greater help from the latter. Owing to the loading of the colon, and the tenacity with which faecal masses will adhere to the mucous membrane, some days may have to be spent in the administration of aperients and in lavage of the colon before it is empty. A small hard adherent mass of faecal material will show the same filling defect as a growth, and imprisoned gas will prevent the entry of the opaque material. Spasm of the colon, especially in heavy smokers, may suggest an organic stricture, and the overlapping of one part of the bowel by another may cause a deepened shadow or prevent a free entry of the barium mixture. I have been misled both by negative and by positive diagnosis made by the radiologist, but I have been far more often aided than hindered, especially if a day-to-day examination of the faeces for blood, when the diet is free from hæmoglobin, has been made. By collating these two methods of examination, radiological and hæmatological, with the clinical history we are able to recognize malignant disease of the colon before a tumour can be felt, and before obstruction has developed, and having regard to the fact that the colon lends itself to removal better than most parts of the body, and that recurrence after early operation is rare, this a great achievement.

Gall Bladder

The recognition of diseases of the gall bladder is now receiving help from the radiologist. In making a diagnosis we are all accustomed to speak of cholelithiasis—to say that a patient is suffering from "gall stones." But I believe that we shall be able before very long to look upon gall stones in much the same way as we now regard hæmorrhage from a duodenal ulcer, or its perforation—that is, as a quite unnecessary complication. Gall stones are the expression of tedious events in a terminal stage. Despite my friend Rosing of Copenhagen, I have unchanged belief in the view that gall stones are the consequence of infections which reach the gall bladder from one or more of several sources. Our business is to search out the inaugural symptoms, the symptoms of infection of the gall bladder, and to use all the means that the radiologist—employing, too, the method of Graham—can

bring to our aid. I look forward hopefully and not without confidence to the day when we shall regard cholelithiasis as a preventable disorder. It is true that the clinical diagnosis nowadays is not often at fault. We are able to predict the presence and the position of stones in the gall bladder or the ducts with a large measure of certainty. Even the pre-calcious stage of this disorder is becoming day by day easier to discover. Though we can clearly see the gall stones on the radiograph in about one-third of the total number of cases in which they are shown by operation to be present, they are not often seen where they are not confidently expected. The indirect signs of cholecystitis are of more interest than the shadow of stones, for they display the changes which the disease has brought about in neighbouring organs by the presence of an enlarged gall bladder, or by the traction exerted by a shrunken gall bladder which has become adherent to them. The advantages of Graham's method would seem to be chiefly in the opportunities afforded for research into the physiological activities of the gall bladder, and into the functions of the liver. We do not yet know in what circumstances and at what rate the gall bladder fills and empties, and we have still much to learn of the secretory activities of the liver. The absence of any shadow after the Graham injection has been made is indicative of a closure of the cystic duct by a stone or by a stricture. But a mistake in the recognition of these two conditions is almost unknown. The danger attaching to Graham's present method appears to be very slight, and doubtless, with enlarging experience, will disappear. The salt used by Graham is useless as a test for hepatic efficiency owing to the fact that its colour is destroyed in serum.

The x-ray examination of the gall bladder after its removal and of the stones which it contained shows that the smaller stones almost always contain nothing but cholesterol. A very few have a nucleus, or an ingredient, of calcium. It is only after a certain size has been reached, and a chronic irritation of the gall bladder has been incessantly at work, that calcium in little spots or in a thin film is laid down on the surface of the stone.

The conclusion I draw from the radiological work done in connexion with cholelithiasis is that it enables a diagnosis to be made which would, in rare instances, perhaps be in doubt, that it discovers the existence of associated lesions in neighbouring viscera, and chiefly that it is a powerful instrument of research in enabling us to discover the composition of stones, and therefore to learn something of the processes at work in their formation, and by Graham's method to add something to our very imperfect knowledge of the functions of the gall bladder and of the liver. In other conditions the help of the radiologist to the clinician is still more invaluable. In diseases of the kidney and ureter, in the discovery of stone within the bladder or of diverticula protruding from it we are even in danger of allowing our clinical diagnosis to ignore the history, and to base itself confidently upon radiology alone. No doubt others are as weak as I am. When a patient complains of pain in the loins I am tempted to ask first what the radiologist says, and to accept his word as law. Indeed, he is so constantly right when the clinician alone would be so often in doubt that here too he is both guide and governor. The use of the "bonnet" which so greatly helped us in the removal of projectiles during the war may well be remembered when the kidney, delivered from the wound, is being searched for stones. And here, too, research work upon the normal and pathological anatomy of the kidney and ureter, after opaque injections have been made, and upon the chemical constitution of stones, has added notably to our knowledge.

One of the most delightful uses to which radiology has been put is that which Sierd introduced for the localization and discovery of tumours of the spinal cord. My knowledge of this comes from Mr. Percy Sargent. I confess that I felt a thrill of pleasure when I first learnt of this most ingenious method.

Limitations

One very important point remains. All the methods, other than the application of our own senses directly to the patient which we so willingly use in the practice of

surgery, are after all mediocrity. They strengthen our clinical acumen by adding weapons of varied and sometimes, in the case of radiology, of immense value. But they all supplement our clinical resource, they do not, and cannot, supplant them. In regard to gastric ulcer I cheerfully acknowledge that the radiologist is, on the whole, a more competent and a more accurate diagnostician than I am. He has pride of place. But I find an occasional case when, being confident of the existence of an ulcer, I learn that the radiologist doubts, or even denies, the diagnosis which nevertheless in operation confirms. I accept with gratitude a positive diagnosis made by the radiologist but if my clinical sense urges me, after the receipt of a negative report from the x-ray department, to hold to my diagnosis, I may find my tenacity rewarded. In a long series of cases the radiologist will, however, prove to be right more often than the clinician.

When the clinical diagnosis of an ulcer, or of a diseased gall bladder, or of an ectopic growth, is not confirmed by the x-ray report, what is to be done? The whole case must once again be reviewed. In cases of gastric ulcer I hesitate to go contrary to the report of the radiologist, but sometimes I am driven by my own confidence to do so. In cases of duodenal ulcer I prefer my own opinion, linked with that of the chemist, to that of the radiologist. If he gives a negative opinion and I am persuaded of the accuracy of my own, I am prepared to act upon it. And I find I am more often right than he is. In gall bladder disease the clinician, if unsupported by the radiologist, should be prepared to act alone. I could quote many instances where patients, including medical men, have heard the diagnosis of cholecystitis from the clinician, and on learning that it lacks confirmation by the radiologist have been hilled into contentment and a dangerous inactivity, only to be roused by a very formidable catastrophe. If the careful clinician has made a diagnosis of cholecystitis or cholelithiasis a report from the radiologist that gives it no countenance should be disregarded. And so it is with suspected malignant conditions of the large intestine. Though a radiological examination often affords the greatest help when confirmed with the clinical history, and with the direct search for occult blood, the earliest and the most certain diagnosis of these diseases, after all, is made when the barrier of the abdominal wall is lifted and an

TUMORS

The treatment of carcinoma wherever it occurs is a disheartening business. The recognition by patients and by medical men of the earlier conditions of malignant disease, even in parts that can be seen or are easily accessible to examination, is unhappily infrequent. It seems almost incredible that patients should allow ulceration of the tongue, for example, to progress to a stage in which remedies are almost hopeless. The diagnosis presents no difficulties, and inspection of the tongue in a mirror ought surely to awaken anxiety. And at every meal time discomforts must be felt or limitations of diet be necessary. When a lump appears in the breast of a woman her natural timidity makes her perhaps, unwilling to submit herself to examination. And when the tumour is plainly felt by a medical man no little time is lost in discussions as to its nature. Nothing but the microscope can settle the diagnosis in a difficult case, to wait for the appearance of those signs which convince the surgeon that the tumour is malignant is to give time for the disease to be disseminated. A review of many cases over a period of twenty years results in this interesting law: "In tumours of the breasts of women over 40 years of age, not less than 80 per cent are malignant, no matter what the physical signs of the tumour may be." Diagnosis, therefore, is largely a matter of the age of the patient. It is a far more reliable guide than any other. Many cases follow upon chronic inflammatory lesions—in the mouth, in the breast, in the stomach, upon the skin, in the colon. Cancer therefore is often a preventable disorder. And in its early stages in most organs of the body it is a curable disorder. To the surgeon two facts about cancer appear indisputable: that it comes as a result of long continued irritation, and that it begins as a purely local disorder and can in that stage be wholly eradicated.

It is pitiable to find so large a number of cases which are inoperable, or which, having been treated by operation, suffer recurrence. To deal with these cases many remedies have been sought. Radium has proved its value in some of them, and the application of x-rays was soon included among our methods. Twenty years ago or more I sent all my breast cases, and all cases in which glands had been removed from the neck after excision of the tongue, to the radiologist. Of the effects produced by the methods of radiology in such cases it was difficult to judge. If the patient remained free from recurrence, one was unable justly to apportion credit between the radiologist and the surgeon, if the disease returned, both had proved powerless. I came tardily and reluctantly to the conclusion then that on the whole more harm than good was done, and I abandoned the method entirely.

When the deep x-ray methods were introduced I felt renewed hope, and with the most skilful and enthusiastic co-operation of Dr. Cooper I have submitted a very large number of patients to his treatment. An exposure to the deep x-ray may be made (a) before operation, (b) during operation, (c) after operation, (d) when operation is impossible.

(a) Before Operation

In my own practice this is not often adopted in cases of cancer, for I feel that if a growth is to be removed it may be possible to eradicate it to day and impossible to-morrow, and I never waste one single day. But in cases of carcinoma of the breast, when the activity of the growth and the rate of its extension seem almost inflammatory, it may be worth while to apply the rays, not so much to the growth as to the area around it, in the hope that the cells in lymphatic vessels, which might be set free to implant themselves upon the surface of a wound, may be destroyed.

In cases of carcinoma of the rectum, or of the uterus, with much induration and thickening around the tumour, and when adhesions appear to be present, the rays may cause a change so great as to make one doubt the truth of the earlier observations. The growth shrinks, loses its induration and fixity, and from appearing irremovable seems now to offer no difficulty. In one case in which, in an enfeebled old woman, much distressed by a teasing diarrhoea, I had performed colotomy, the growth entirely disappeared. I had removed a gland at the time of operation, and the diagnosis of carcinoma was not in doubt. No doubt the growth will reappear, but its complete removal is an evidence of the great effect which the rays are able to produce. In all cases of splenic enlargement one or more exposures to x-rays are given. The reduction in the bulk of the spleen is almost incredible from filling the whole abdomen the organ shrinks until a lump the size of a golf ball is felt below the costal margin. Then the spleen may be removed with a safety and with such ease as could not be claimed for any operation upon it in its original state.

(b) During Operation

In cases of Crile's operation upon the glands of the neck, and in cases of carcinoma of the breast, I think we might more often expose the entire area of operation to the rays before we close the wound. I have done this in a number of cases, and though it is impossible accurately to gauge its value, on theoretical grounds it certainly appears a very desirable procedure. I have long felt disheartened by our inability to perform more often than we do radical operations for carcinoma of the stomach. I therefore determined to enlist the help of the radiologist. The application of x-rays to the surface of the abdomen, though it may rarely do good in these cases, does sometimes appear to do him. I tried a new method. While the abdomen was opened and the stomach exposed I moved the patient to the x-ray room, and there, bringing the growth as far as possible into a widely opened wound covered by a single layer of mercurochrome gauze, I applied the lamp directly to the stomach for a period of forty minutes. The abdomen was closed. Seven weeks later in one case, nine weeks later in another, I reopened the abdomen and found the growths so changed and shrunken that I was able to remove them, with all their attached glands. Two operations of gastrectomy in this way were performed in 1923 and to-

day both patients are alive and well. One has gained 33 lb in weight, another 9 lb. In both two transfusions of blood were given—one at the time of the x-ray exposure and one before the removal of the stomach was undertaken.

(c) After Operation

As soon as the wound is healed after removal of the breast a course of treatment by the radiologist is now advised in all cases. The hope we entertain is that cancer cells in the neighbourhood of the wound will be killed, and that recurrence may be so prevented. Of the prophylactic value of the rays we cannot speak with any certainty. A local recurrence after an operation for mammary carcinoma is in any event so rare that a very long series of cases would be necessary to establish the value of post-operative radiation. But, again, on theoretical grounds the treatment appears so rational that I should not feel content to omit it.

It is perhaps desirable to urge once again the necessity for an x-ray examination of the chest and neck before any operation for carcinoma of the breast is undertaken. The search for metastatic deposits in outlying regions should invariably be made before removal of the primary source is undertaken. When recrudescence of the growth has taken place in the neighbourhood of the wound, or when glands appear in the neck, radiation will often produce the most remarkable results. I have known multiple nodules scattered widely over the chest wall to disappear completely, and to remain absent until the patient's death in consequence of visceral deposits, and glands grossly enlarged and causing pain in the neck and head are diminished in size or caused to vanish, and the lancinating pains soon disappear.

(d) Inoperable Cases

A visit to the radiological department engaged in the treatment of these cases is a depressing experience. Cases for which the surgeon can do nothing and cases for which he has done all he can, are sent to this last resort. All the surgical outcasts find refuge here. If radiology could do nothing for them no blame could attach to it, for more unpromising derelict material it would be impossible to find. Yet something is wrought upon these cases that at times approaches the miraculous. Growths shrink and wither away, and foul and extensive ulcers make vigorous attempts to heal, and haemorrhage from excavating caverns ceases entirely. Growths of the thyroid seem to melt away, and growth of the prostate, hard, fixed, and painful, may disappear very quickly. But the return is not long delayed. The most dramatic result I have ever seen was in connection with a carcinoma of the thyroid as large as the patient's head which disappeared almost entirely within a month, only to return with almost equal haste and quickly to prove fatal. There are, of course, many disappointments, and at present one is not able confidently to reckon upon any improvement in the individual case, but the fight for each one is always worth while.

The effects produced upon the patient are sometimes apt to be serious unless great care is taken. The red cells are so diminished in number that great enfeeblement results. I have many times given one or two transfusions of blood in patients who have to submit to x-ray treatment, and hypodermic injections of udon are administered regularly, and most patients are given artificial sunlight baths.

The gifts of radiology to medicine and to surgery have been most lavishly bestowed. When we consider that this science is a newcomer into the fields of diagnosis, of therapy, and of research, the results obtained in so short a time are surely matters for which humanity at large may feel profoundly thankful. If I may for one moment arrogate to myself a greater authority and a wider responsibility, I should like to offer to you, gentlemen, in the name of all your colleagues, my respectful homage for the immense benefit you and your forerunners have already conferred upon mankind, and to express my confident prediction and my warmest hopes for the continued and beneficent progress of the science which you so worthily represent.

THE CLINICAL VALUE OF THE VAN DEN BERGH REACTION FOR BILIRUBIN IN BLOOD

WITH NOTES ON IMPROVEMENTS IN ITS TECHNIQUE

BY

J. W. McNEIL, M.D., F.R.C.P.,

DEPUTY DIRECTOR OF THE MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL, LONDON,
AND

CHRISTOPHER S. KEEFER, M.D.,

ASSISTANT IN MEDICINE, JOHN'S HOPKINS HOSPITAL, BALTIMORE

The reaction of Hujmans van den Bergh for the recognition and estimation of bilirubin in blood serum, plasma, and other albuminous fluids of the body is now well known to clinicians. More than two years have elapsed since the method was first described in the English language, and since then ample opportunity has been afforded of testing its applications in different directions.

It is not proposed to discuss here the influence of the method on research work in connexion with hepatic disease and bile-pigment metabolism, although this influence has already been great. It seems worth while, however, to reconsider, after two years, the present position and value of the test in its purely clinical aspects, and whether it has been of much service in the routine study of hepatic disease. Certain improvements in technique, which must add greatly to any merits possessed by the test, are also referred to.

During the past two years one of us (J. W. M.) has received a great deal of correspondence from workers, both in America and Great Britain, who have made use of the test. Various points of difficulty have been raised, some easily solved by the results of experience or by experiment and some not easily explainable at a distance without knowledge of the reagents used. From this correspondence, however, several important points have emerged, and require discussion.

Publications on the purely clinical application of the test are already numerous, especially in Germany. No full bibliography need be attempted, but ample records of clinical results are contained in the following:

Feigl and Querner (1919) Lepehne (1920, 1921) Rosenthal and Holzer (1921) Brülé Garban and Weissmann (1922) Andrews (1924) and Hughes (1924). Application of the test to special clinical problems has been made by Strauss and Buckmann (1922) Girard (1924) Schamberg and Brown (1924)—latent and overt salvarsan (arsphenamine) jaundice Schiff and Ehrsberg (1922)—catarrhal jaundice Fishberg (1921)—jaundice in myocardial insufficiency Andrews (1924)—peculiar diazo reaction in uraemia Brown Ames Warren, and Peabody (1925)—study of the blood pigments in pernicious anaemia.

OTHER CLINICAL TESTS FOR BILIRUBIN IN BLOOD SERUM

Since the introduction of the van den Bergh reaction a number of other colorimetric methods for the estimation of bilirubin in blood serum have been developed, most of them designed for purely clinical use. One well known and simple method is that of Meulengracht (1921), in which the yellow serum is compared with a standard solution of potassium bichromate. By this method quantitative changes in the bilirubin content of a serous serum are easily determined, but the presence of leucins or carotins in a serum are obvious sources of error. Moreover, the Meulengracht test is unsuitable for the detection of latent jaundice, and gives no qualitative differences such as are brought out by the van den Bergh technique. Van den Bergh has stated (1924) that after an examination by Muller (one of his co-workers) of all the simple colorimetric methods, the conclusion was reached that the original diazo method is still the best, and the present writers are in agreement with this. One other test for bilirubin in blood serum of recent introduction may be referred to here.

This method introduced by Fouchet (1918) has attracted considerable attention particularly in France and although not so delicate as the van den Bergh reaction it is said to give a positive result in a dilution of 1 in 60,000 of bilirubin. It consists essentially in mixing equal volumes of the serum with a reagent made up as follows:

Trichloroacetic acid	5 grams
Ferric chloride solution	2 c cm
Water	20 c cm

The mixture of serum and reagent is stirred with a glass rod, and in the presence of bilirubin a greenish blue colour appears. The maximum reaction is said to be obtained after twenty minutes, and an almost instantaneous coloration in concentrations of bilirubin of less than 1 in 20,000. A scale of standard units of male elute green diluted with pure white lead has been devised to give a rough quantitative method for clinical use. This test does not bear comparison with the diazo-reaction of van den Bergh for clinical purposes, but is important as affording a good and delicate confirmatory test of the presence of bile pigment in blood serum.

DIFFICULTIES IN THE TECHNIQUE OF THE VAN DEN BERGH REACTION

In an article written by one of us (J. W. M.) in 1923 time limits for the development of different varieties of the "direct" van den Bergh reaction were given as follows:

Prompt Direct Reaction—Bluish violet colour, beginning immediately and maximal in ten to thirty seconds.

Delayed Direct Reaction—Reddish coloration, gradually deepening to become more violet, begins only after one to fifteen minutes, or even much longer.

Biphasic Direct Reaction—Reddish colour appears at once, and either slowly or quite rapidly deepens to violet.

These directions were founded on a moderate experience and formed an average of the results obtained up to that time. It was not expected, however, that different observers, using different reagents, would obtain results within these exact limits, and it was believed that each observer must to some extent interpret his results from his own experience. Andrews (1924), after considering the above directions and the time limit of thirty seconds given for the prompt direct reaction, states:

I have hardly ever found such a reaction and even with fresh bile the colour goes on changing after thirty seconds. If a red colour begins to appear within thirty seconds I consider that the direct reaction is positive.

One point of great importance for the development of the van den Bergh reaction has not been emphasized hitherto, but must always be considered in the interpretation of results. The interval of time between the withdrawal of blood and the carrying out of the test must be known, and should for routine clinical purposes be as short as possible—certainly not longer than two hours or thereabout. Experience has proved that serums showing a prompt direct reaction when tested at once give a slow and often long drawn-out result when retested on the following morning. This has prevented one of us (J. W. M.) from dealing with serums forwarded by post for control examination.

Differences in reaction, either to the acid or alkaline side, are of great importance for the development of the correct colour of the azo bilirubin compound. This can easily be proved after completion of the indirect reaction and addition of diazo-reagent to the supernatant fluid, by testing the effects of very dilute acid alcohol or alcoholic-ammonium hydrate on the colour developed in the test. This point emphasizes the need for care and cleanliness in the reagents and glassware employed.

The occurrence of haemolysis in a serum interferes with the colour reaction in the test, and in recent work we have used oxalated plasma only. In practice, 0.2 c cm of a 10 per cent solution of potassium oxalate is placed in a small wide loosely corked bottle, and evaporated to dryness during sterilization of the bottle. The oxalate is in this way finely distributed over a large surface, and will prevent coagulation of 10 to 15 c cm of blood, if the bottle be shaken.

IMPROVEMENTS IN TECHNIQUE

A Lepehne's Technique for the Qualitative Reaction

This method has simplified the reading of results in the direct reaction, since it gives standards for comparison both in respect of the rate of development and time of completion.

Three small test tubes are taken. The first or control tube contains plasma diluted with water. The third tube contains plasma in which the diazo reaction is allowed to develop and reach its maximum by the method described below. The second tube contains plasma to which diazo reagent is added last of all the character of any reaction being watched in comparison with the control tube (I) and the completed reaction (III).

Lepehne has applied an interesting observation of Adler and Strauss (1922) as an aid to completion of the reaction in tube III. These writers found when attempting to

solve the problem of the two varieties of bilirubin apparently differentiated by the diazo reaction, that the addition of a small amount of caffeine-sodium-salicylate induced in many icteric serums an increased rapidity in development of the maximal colour. They quote, for example, one serum giving a delayed reaction (16 units) only, the direct reaction being negative. Addition of a trace of caffeine-sodium-salicylate brought about a prompt direct reaction, maximal in ten seconds, while no change in colour ensued for at least two minutes in the absence of the drug. The original paper should be consulted for an account of the work leading indirectly to this observation. We have made use of caffeine-sodium-salicylate in a number of experiments, but find that the action stated above is by no means constant, at least with the samples of the drug used by us. In some serums the hastening of the colour reaction is definite, at other times no such effect was observed.

The technique of Lepelme, however, is so easy, and gives such good standards for comparison, that we recommend it strongly as the best method of carrying out the direct qualitative test.

Method

0.25 ccm of the oxalated plasma is placed in each of three small test tubes. To tube I (the control) add 0.2 ccm of water. Drop a small flake of caffeine sodium salicylate into tube III (shake to dissolve completely), and then add 0.2 ccm of fresh diazo reagent. In this tube a prompt or rapidly developing reaction may be obtained, quickly arriving at its maximum. Some times in our experience, the effect of the drug is negative, but in any case ample time should be allowed for the colour reaction in tube III to be completed.

To tube II then add 0.2 ccm of fresh diazo reagent watching and timing the development of any prompt or biphasic reaction in comparison with the control tube I, and the completed reaction in tube III.

B Improvement in the Quantitative Estimation of Bilirubin

It has always been insisted on by van den Bergh that the estimation of bilirubin made possible by the indirect reaction is by no means accurately quantitative. He states (1924) that he has always called it simply "an estimation," and not a quantitative determination. This is because some bilirubin is always carried down and lost in the albuminous precipitate during the performance of the indirect reaction. This is particularly noticed in serums giving a prompt direct reaction, where the loss may be considerable, and the precipitate coloured bright yellow. In serums giving a delayed reaction the loss is much less. Where bilirubin is present abundantly the loss can be reduced by previous dilution of the serum with water, but this method is inapplicable where only small amounts of bilirubin are present.

This difficulty has been solved by Thannhauser and Andersen (1921), who have pointed out that all the azo-bilirubin can be retained for estimation in the supernatant fluid if diazo-reagent be first mixed with the test plasma to allow "coupling" to take place, and then alcohol and saturated ammonium sulphate solution be added. In this way after shaking and centrifuging, a layer of clear ammonium sulphate solution is left at the bottom of the centrifuge tube, above this a white albuminous precipitate, and on the surface the clear reddish-violet alcoholic solution of azo-bilirubin. By this technique all the bilirubin from plasma giving a direct prompt reaction is available for estimation. This method is unnecessary for serums giving the delayed reaction only, where the loss of bilirubin in the albuminous precipitate is slight.

Method

The method may be summarized as follows. To 1 ccm of serum add 0.5 ccm of diazo reagent. After a minute or two add 2.5 ccm of 95 per cent alcohol and 1 ccm of a saturated solution of ammonium sulphate. Mix and centrifuge. If the colour of the supernatant fluid is too intense for quantitative estimation, dilute with alcohol 2 parts, water 1 part.

The rationale of this method need not be discussed in detail. It may be mentioned, however, that pure bilirubin is scarcely soluble in alcohol, and in the ordinary indirect reaction it is astonishing how much bilirubin remains in the alcoholic supernatant fluid after precipitation of the protein. Azo bilirubin on the other hand, is freely soluble

in alcohol. Moreover, Adler and Strauss have pointed out that in serums from cases of obstructive jaundice associated with a prompt direct reaction the globulin content of the serum is always diminished. They found that salting out the globulin fraction with magnesium sulphate hastened the development of the direct diazo reaction under experimental conditions. It seems likely that the removal of globulin, or of water, or both, by ammonium sulphate in the method suggested by Thannhauser and Andersen has something to do with the results obtained, but this question requires further investigation. In this method some water certainly goes over into the saturated ammonium sulphate solution, so that the dilution of the serum in the supernatant alcoholic solution is really slightly less than 1 in 4. For practical purposes, however, the dilution of the serum in making the estimation may safely be taken as 1 in 4.

Table contrasting the Results of the Original Method of van den Bergh (I) and the Thannhauser and Andersen Modification (II)

Disease	Type of Reaction	Bilirubin Units	
		I	II
Lost salvarsan jaundice	Direct—either prompt or biphasic	15	60
Pot salvarsan jaundice		10	55
Carcinoma—head of pancreas		30	170
Carcinoma of liver—metastatic		70	150
Catarrhal jaundice	Indirect only	45	55
Ditto—end stage		05	05

C Improved Standard Solution

The standard ethereal solution of monorhodanate, originally used by van den Bergh for estimation of bilirubin in "units," has also been a difficulty and source of trouble. In a review on jaundice (1923) some of the criticisms of this standard solution were briefly discussed, and it must be admitted that even when the test is carried out as carefully as possible with clean glassware and carefully prepared reagents, the colours of the test solution and of the standard may not accurately match. Slight changes in reaction of the various reagents may, as already noted, account for this, and one practical point noticed by us is that for diluting the test fluid, in order to bring it within the range of the standard solution, alcohol must be used and not water, or a change in colour tone at once ensues.

The practical difficulties with the ethereal standard solution do not end here. It must be freshly prepared for each set of estimations, and evaporation must, of course, be prevented. During the past summer Professor Højens van den Bergh has informed us of a new artificial standard solution which he and Muller have found can replace the monorhodanate ethereal solution. So far as we are aware this standard has not been published, so we wish to acknowledge its source. The new standard is made up by dissolving 2.161 grams of anhydrous cobaltous sulphate in 100 ccm of distilled water. This solution gives a colour equivalent to 1 unit of bilirubin (1 in 200,000), and is almost identical in colour with the original monorhodanate standard. It is permanent if kept in the dark, and the writers have found it entirely satisfactory in practice, and in direct comparison experiments with the original standard. The cobalt salt must be anhydrous, and at first the supply of the new cobalt standard should be compared with the old ethereal standard and any necessary adjustments in colour made. We have found slight adjustments necessary with the cobalt salt used by us. The ideal thing would be to compare the standard with the diazo-reaction given by a solution of 1 in 200,000 of pure bilirubin, but pure bilirubin is practically unobtainable.

It seems certain that this new and permanent standard must replace the older ethereal solution. If a Hellige wedge colorimeter be used one wedge can be kept full and sealed, and is then available at any time.

SUMMARY AND CONCLUSIONS

1 The van den Bergh reaction is the best method so far available for the clinical investigation of the bilirubin

content of blood serum or plasma. It has numerous advantages over other tests which have subsequently been proposed: (a) its extreme delicacy, (b) is not given by other yellow substances which may colour the plasma, (c) gives important qualitative distinctions between certain forms of icterus, (d) can now be used for a satisfactory quantitative estimation of bilirubin.

2 The qualitative reaction may enable a positive diagnosis of obstructive or of haemolytic icterus to be made. Painful anaemias, except in the stage of rapid temporary improvement, can be distinguished from secondary anaemias. In some diseases (for example, catarrhal jaundice, subacute liver atrophy, cardiac failure) the reaction may pass through all the stages from completely delayed to prompt direct, as the disease progresses. As a rule, however, in the commonest type of jaundice (the toxic and infective hepatic group) no information of any diagnostic or prognostic value is given to the clinician.

3 The test is of great practical value for the detection of "latent" prejudice

RADIOLOGY OF THE GALL BLADDER BY GRAHAM'S METHOD *

HENRY COHEN, M D ,

BRIGHT MEMORIAL RESEARCH FELLOW HONORARY ASSISTANT PHYSICIAN
LIVERPOOL ROYAL INFIRMARY,
AND

AND

R E ROBERTS, M D , B Sc , D M R L ,

HONORARY RADIOLOGIST, LIVERPOOL ROYAL INFIRMARY

It is generally admitted that the routine examination by x-rays of the gall bladder area for the presence of stones is subject to serious limitations as regards diagnostic value, for even by means of good radiographs and skilful interpretation their existence can only be clearly demonstrated in, at the outside, 35 to 40 per cent of the cases where they are present. Though an x-ray finding if positive is of definite diagnostic value, a negative finding does not exclude the presence of gall stones and must be ignored.

In the interpretation of shadows found in the gall-bladder, there are two types sufficiently characteristic to be practically diagnostic of gall stones. These are the annular or ring-like shadow (Fig 1) and the cluster of shadows resembling a bunch of grapes (Fig 2). The finding of these shadows in a radiograph of the right upper abdomen is practically certain evidence of the presence of gall stones, especially if, by radiographs taken in different positions of the body, they are shown to be situated nearer the front of the abdomen than the back. Other atypical shadows may be found in the region of the gall bladder which call for more serious thought and skill in interpretation before they can be taken as evidence of gall stones.

A large number of gall stones, however, are not sufficiently opaque to rays to throw any shadow at all when they are in the body. Some, indeed, are so translucent that even when the gall bladder containing them is removed and radiographed they are no more opaque than the bile or the walls of the gall bladder by which they are surrounded, in

4 Various alterations in the original technique have improved and simplified its use in clinical mechanics.

fact, they may be even less opaque, and may show in the radiograph of the free gall bladder as translucent areas in the shadow of the more opaque gall bladder and bile.

In 1913 Holland and Williams investigated the factors underlying this varying degree of opacity of gall stones. They found that the opacity depended on the proportion of the pigment and other salts of calcium. Those containing a large proportion of cholesterol were the most translucent, while those containing a large proportion of pigment or other salts of calcium were the most opaque. The calcium salts are often deposited at the periphery of the stone and so give rise to the characteristic annular shadow.

Apart from the direct x-ray evidence of gall stone, the existence of a pathological condition of the gall bladder may often be suspected from abnormalities of contour, position, or function, of the stomach or duodenum, found during the examination of the gastro-intestinal tract by the opaque meal, or by a process of elimination, by means of x rays, of gastric, duodenal, and appendiceal lesions, and of urinary stones.

GRAHAM'S METHOD OF EXAMINATION

The method of radiologically investigating the gall bladder, observations on which we wish to record in this paper, is attributable to Graham of St Louis, USA. It is based on the use of a salt opaque to x rays which, when injected into the blood stream, is excreted by the liver, enters the gall bladder, and is there concentrated, thus rendering the gall bladder under normal conditions opaque to x rays.

Rountree has shown that certain dyes — for example, phenol tetrahydrophthalein — when injected into the blood stream, are excreted almost entirely by the liver. The rate of disappearance of this dye from the blood as a test of liver function and that tetrahydro-phenolphthalein and sodium — were excreted by kidney and were opaque to x rays although more opaque, was, in for general use. More recently after a careful chemical and

experimental comparison of the bromine and iodine salts, state their preference for the latter. In our investigations the sodium salt of tetra-bromophenolphthalein has been used throughout. It was obtained as a crystalline powder from the Mallinckrodt Chemical Works of St. Louis.

Method followed in this Inquiry

Our procedure was as follows:

1 All cases were first examined radiologically by the ordinary direct method for gall stones. In every case of our series which was operated on, except one, where a doubtful and non diagnostic shadow was seen in the region of the gall bladder, the result of this examination was entirely negative.

2 The cases were then examined radiologically by Graham's method of intravenous injection of the dye. The technique adopted was as follows:

No special preliminary preparation was made except that during the four hours preceding the injection no food or fluid was allowed.

Five grams of the salt were dissolved in 40 ccm of distilled water and sterilized by boiling for twenty to thirty minutes. This solution was very slowly injected intravenously in two doses, the second being given half an hour after the first. In view of the danger of necrosis which might follow extravasation of the dye into the subcutaneous tissues, the needle was inserted separately into the median basilic vein and blood was allowed to flow freely from it before attaching the syringe. It is most important that the rate of injection should be slow if untoward symptoms are to be avoided. The injection of the dye was followed by a few cubic centimetres of sterile normal saline solution to avoid leakage of the salt when the needle was removed.

During the first day no food other than a glass of milk at lunch and in the evening was allowed. During the second day ordinary fish diet was given. For the forty-eight hours following the injection 40 grains of sodium bicarbonate were given every three hours during the day.

Two and a half hours after the injection (that is one and a half hours before the first radiographic examination) 0.5 ccm of pituitrin was given hypodermically, followed three quarters of an hour later by a simple enema.

Radiographs of the gall bladder area were taken four, eight, twenty-four and thirty-six hours after the injection.

Reaction following Injection

The injections occasionally gave rise to unpleasant symptoms of vasomotor shock—such as pains in the back, dizziness, nausea, vomiting, cyanosis, coldness, or "queer feelings"—associated with a lowering of the blood pressure, a preliminary rise was sometimes observed.

We have encountered no serious symptoms in our cases, only a slight reaction occurred in most of them, serious symptoms can be avoided by slow injection. If necessary a hypodermic injection of 10 minims of a 1 in 1,000 solu-

tion of adrenaline hydrochloride may be given, we have never had to use this, occasionally we have given brandy after the injection.

The X-ray Appearances of the Normal Gall Bladder after the Injection

The shadow of the gall bladder containing the dye, which has been excited by the liver, can be made on four to five hours after the injection has been given.

1 The shadow increases in intensity, owing to the progressive concentration of the dye, up to anything between eight and twenty-four hours. The shadow is homogeneous, oval or pyriform in shape, and of even contour. After this the shadow became less intense as the dye becomes diluted and passes out.

2 The gall bladder shadow also varies in size, being larger at the earlier examinations (five to eight hours), and then becomes gradually smaller. This variation in size is important evidence of normal distensibility and contractility of the gall bladder.

Physiological Requirements

Before the shadow of the gall bladder containing the dye can be produced three requirements must be fulfilled—namely:

(1) The dye must be excited by the liver. This will not take place if there be, for example, gross cirrhosis or carcinoma of the liver.

(2) The dye must be able to pass into the gall bladder. This will not take place if there be obstruction to the cystic duct or common bile duct, such as might be caused by gall stones, adhesions, papilloma, thickened bile, catarrh, etc., or if the gall bladder be filled with gall stones or growth.

(3) The dye must become concentrated in the gall bladder, by absorption from the gall bladder mucosa, contraction of the gall bladder, and retention of the dye for a sufficient length of time. This will not take place if there be chronic cholecystitis or if there be a fistula connecting the gall bladder directly with the gastro-intestinal tract and so allowing the immediate or early escape of the dye from the gall bladder.

The Abnormal Gall Bladder

If there is any obstruction due to gall stones, adhesions, thickened bile, etc., we may find either that the gall bladder fails to fill at all with the dye and so gives no X-ray shadow, or that it fills scantily, giving a persistently faint shadow, or that there is delayed filling.

Another evidence of pathology is marked delay of emptying, or an unduly large size of the shadow, due to loss of elasticity of the gall bladder walls. On these may be a

RESULTS OF INVESTIGATION

Of the series of cases in which the gall bladders were investigated by Graham's method ten were subsequently operated on and four were not operated on. Our radiological findings and deductions together with the operative or other findings are shown in Tables I and II.

In only one of the ten patients operated on were the surgeon's findings at variance with our radiological deductions. In this case (J O) the evidence obtained by an examination of the gall bladder by Graham's method (on two occasions) indicated a pathological condition of the gall bladder. Yet at operation no gross evidence of pathology was obtained. The only abnormality found was a slender adhesion over the common duct, when this had been divided the gall bladder, previously full, was seen to empty. It is doubtful whether this could be sufficient to prevent the dye from passing into and being concentrated in the gall bladder. We trust that a further examination of the gall bladder by Graham's method after the patient has recovered sufficiently from the effects of the operation may throw further light on the question.

CONCLUSIONS AS TO THE VALUE OF GRAHAM'S METHOD

In estimating the value of this method of radiologically examining the gall bladder three facts must be borne in mind:

1. That only a maximum of 35 to 40 per cent of gall stones show evidence of their presence by the ordinary method of direct radiography.
2. That a negative finding by the ordinary method does not exclude the presence of gall stones.
3. That "gall stones are incidental and not essential to a cholecystitis which may necessitate surgery."

It is therefore in those cases which by the ordinary direct method of radiography fail to show the presence of gall stones that this new method is of particular value. By no other means short of operation can we ascertain whether this negative finding signifies a normal condition of the gall bladder or not. In other words, it should be used as an adjunct rather than as an alternative to the ordinary method of examination.

A striking feature of the cases shown in Table I is the fact that of all seven cases where a pathological condition of the gall bladder was found at operation, only one case gave the slightest evidence of this before injection, whilst all gave evidence of a pathological condition when examined by Graham's method. The two cases where a definitely normal gall bladder was found at operation both gave definite indication of a normal gall bladder by Graham's method.

The single remaining case where a pathological gall bladder was deduced from the findings by Graham's method, and where at operation no gross evidence of a pathological condition was found, as already stated, needs further investigation.

However, the successes encountered in all the other cases are, in our opinion, a striking testimony to the value of this method as a diagnostic aid in the examination of the gall bladder.

We wish to express our thanks to Dr Leggate for his valuable assistance and to those physicians and surgeons of the Liverpool Royal Infirmary who have allowed us to investigate their cases.

LEPTOSPIRA IN LONDON WATERS

By

EDWARD HINDLE, M.A. Cantab, Ph.D.,

FRSE,

MILNER RESEARCH FELLOW, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

THE occurrence in the British Isles of sporadic cases of spirochaetal jaundice, although apparently few in number, shows that under certain conditions the disease may be acquired in this country, and therefore any observations throwing light on the origin of these outbreaks may help to eradicate the infection. The following notes on the presence of a leptospira, morphologically identical with *Leptospira icterohaemorrhagiae*, in London tap water, Thames river water, and water from several other sources in the neighbourhood, are published in the hope that they will draw attention to these interesting organisms, which under certain conditions may assume grave importance from the point of view of public health.

Attention was first directed to this subject by the discovery of leptospira in one of Professor Leiper's cultures at the London School of Hygiene and Tropical Medicine, which had been prepared to show the ciliated embryos of the broad tapeworm, *Dibothriocephalus latus*. The faeces of a patient infected with this worm, and containing large numbers of ova, had been mixed with ordinary London tap water in a Petri dish, then incubated at 30° C for sixteen days, and subsequently kept at room temperature for about one week. When examined by dark-ground illumination, the water was found to be swimming with leptospira, there being as many as thirty to forty organisms in each field of the microscope. Under the impression that the leptospira might have had a human origin, the faeces of a number of patients in the Seamen's Hospital, and also from other sources, were mixed with tap water in Petri dishes and the mixtures incubated at 25° C. In every case without exception large numbers of leptospira appeared in the water after an incubation period of ten to fourteen days. Subsequently cultures were prepared by mixing faeces with boiled tap water and incubating, when it was found that these organisms never appeared, thus showing that they were present in the water and not in the faeces. Finally, cultures were made by mixing tap water with faeces, both human and animal, which had been sterilized by boiling, and in every case leptospira appeared after incubating at 25° C for not less than ten days.

From these experiments it was evident that leptospira is present in London tap water, and an attempt was made to determine in what numbers. Although, subsequently, leptospira was found in the slime on the inside of a dripping tap in the laboratory, the direct examination of water under the microscope gave negative results, even

after centrifuging. Therefore a mixture of sterilized water and sterilized faeces was poured into a number of Petri dishes, and subsequently a measured quantity of unboiled tap water added to each, the resulting mixture was incubated at 25° C. It was found that the addition of less than 0.5 c.c.m. of tap water produced inconsistent results, whilst the addition of this amount, or more, invariably resulted in the development of leptospira. Consequently, at the time of the experiment (March) London water must have contained approximately two leptospira in every cubic centimetre.

Subsequently water from other sources was examined, and by employing the method above described leptospira were found in the following: Tring tap water, a rain-water tank in Major S. S. Flower's conservatory at Tring, and water storage tanks at a school in Buckinghamshire. In addition, these organisms were found by direct examination, in London sewage water, in Thames river water off the landing stages at Gravesend and Tilbury respectively, and in the sludge at the outlet of one of the main tanks in the aquarium of the London Zoological Gardens, which was examined through the kindness of Mr. E. G. Boulenger. Finally, my friend Dr. A. Robertson drew my attention to the presence of leptospira, in considerable numbers, in the sludge on the inside of a bowl which received the water draining from the melted ice of an ice-chest in the laboratory.

Culture Experiments

Up to the present I have not succeeded in isolating a pure culture of this water leptospira, and therefore it has been grown only in the presence of other bacteria. All attempts to grow it on any of the ordinary culture media used for *L. icterohaemorrhagiae* failed owing to the more rapid growth of the contaminating bacilli and cocci, which decomposed the media before there was any sign of leptospira.

By far the simplest and most successful way of growing these organisms is the coprozoic method mentioned in the earlier part of this article. A portion of human faeces about the size of a pea is mixed in a Petri dish with about 20 c.c.m. of the water to be examined and the mixture kept in the dish at a temperature of 25° to 30° C. Leptospira can generally be found after ten days, and reach their maximum growth about the twentieth day. They usually persist for a period of four to five weeks, gradually diminishing in number, until they seem to disappear, about two months after the preparation of the culture. This disappearance, however, is only apparent, due possibly to the organisms becoming so scanty that they are not easily detected. In order to produce their reappearance it is only necessary to add a small quantity of fresh faeces and continue the incubation at 25° to 30° C.

With this method the organisms can readily be obtained in considerable numbers, and it affords a convenient way of growing them for demonstration. The cultures should be kept either in the dish or in a shaded corner of the laboratory, for exposure to a bright light is rapidly fatal. It is essential to employ Petri dishes, as the same mixtures of tap water and faeces, when placed in test tubes, or flasks, and incubated at 25° C. never showed any development of leptospira. Moreover, when a culture containing large numbers of these organisms was poured into a test tube the leptospira gradually lost their motility and died off in four or five days. In parenthesis, it may be noted that this property of requiring a large surface and not growing in tubes is in marked contrast with that of *L. icterohaemorrhagiae* cultured on Wenyon-Noguchi medium, in which Dr. Okell has found that although growth takes place readily in tubes, the organism does not grow in Petri dishes or Roux bottles exposing a large surface. Obviously, it is difficult to compare the conditions when one organism is growing in association with many kinds of bacteria and protozoa, whilst the other is growing in pure culture, but the ordinary pathogenic strain of *L. icterohaemorrhagiae* may be grown in a mixture of faeces and water, and in these circumstances requires the same large surface as the water leptospira.

The luxuriant growth of leptospira in the presence of

faeces may be due to the production of sulphuretted hydrogen in the water, for Dobell¹ observed that this substance favoured the growth of other water spirochaetes, and the same effect has been noticed by Zucker². These organisms will also grow in a 0.1 per cent solution of potassium nitrate in sterile tap water, but only comparatively small numbers have been obtained in this medium. The food supply of organisms growing in such a medium is a little obscure, the leptospira may obtain its nourishment either from traces of organic matter present in the water, or by synthesis of food substances from the inorganic salts. Further experiments are necessary to decide this question, which is of some interest from a theoretical point of view.

Filtration Experiments

The water leptospira will pass through an L3 Pasteur Chamberland filter, and may be observed by direct examination of the filtrate. With an L5 filter of the same make leptospira, as such, could not be detected in the filtrate, even after employing the centrifuge. Nevertheless, when the filtrate was poured into a Petri dish and incubated for about ten days at 25° C., leptospira appeared in the liquid. This experiment has been repeated successfully on three separate occasions, and although it is conceivable that leptospira, as such, may have been present in the filtrate in extremely small numbers, so that they were almost impossible to detect by microscopic examination, the more probable hypothesis is that the organisms were present in some other form. The L5 candle is of such fine texture that it is very difficult to believe that an ordinary leptospira could pass through, and the negative results of direct examination of the filtrate support the view that some other stage must have been present.

Animal Experiments

The results of these few experiments are inconclusive, as up to the present I have not succeeded in isolating a pure culture of the water leptospira, and therefore the animals have been inoculated with a mixture of organisms. In no case were leptospira recovered from the inoculated animals, except in three guinea-pigs which died the day after an intraperitoneal injection of 4 c.c.m. of a water culture. The peritoneal fluid of these animals, examined after death, contained actively motile and apparently healthy leptospira. In addition, the following results may be mentioned:

(a) Two guinea-pigs each inoculated intraperitoneally with 0.5 c.c.m. of a suspension of leptospira in water. Both showed febrile symptoms and one died on the tenth day with general darkening of the viscera but subinoculations into two other guinea-pigs gave negative results. The other individual showed rectal haemorrhages on the twelfth, thirteenth, and fourteenth days but no other symptoms.

(b) A young guinea-pig was given by mouth 4 c.c.m. of a suspension of leptospira in water. Its temperature gradually rose to 104° F. and was accompanied by epistaxis on the ninth day. Two days later it was killed and showed slight jaundice and two haemorrhagic spots on the lungs. Blood from the heart and liver was inoculated into two other guinea-pigs, both of which showed febrile symptoms and one of them had rectal haemorrhages on the seventh to the tenth days inclusive.

Owing to the necessity of bringing the investigation to a premature termination, due to the author's sudden departure for China, it has not been possible to continue these experiments, and it is doubtful whether any conclusions can be drawn from the results. Case (b) is the most suggestive, as the symptoms resembled those of a mild case of spirochaetal jaundice, and subinoculations produced fever, in one case accompanied by rectal haemorrhages. The difficulty of recovering leptospira from inoculated guinea-pigs is not sufficiently recognized by authors who have worked with exceptionally virulent strains. Buchanan³ only recovered the organism from one guinea-pig out of 44 inoculated with leptospira from proved cases of spirochaetal jaundice, which shows the necessity of long-continued observations before their presence can be definitely excluded. Up to the present very little attention has been paid to the minor clinical symptoms of guinea-pigs

inoculated with leptospiira, but in view of the existence of strains with varying degrees of virulence, they would probably repay closer attention.

DISCUSSION OF RESULTS

Although water leptospiira have been recorded from various parts of the world, the only record, so far as I am aware, of their occurrence in this country is by Coles,¹² who found them at Bournemouth. J. G. Thomson and D. Thomson² described "a new variety of *Treponema* found in an old specimen of human faeces," which is almost certainly the organism under discussion, but assumed that it came from the faeces and not from the tap water in which the faeces had been kept. In addition, the interesting observations of Buchanan³ demonstrated the existence of a free living leptospiira in the slime on the roofs of coal mines in East Lothian. In the latter case, although the organisms were not discovered in surface water, there is presumptive evidence, in view of their habitat, that they are identical with the water leptospiira.

Considering the variety of sources from which this leptospiira has been obtained it is evidently a very widely distributed organism, and there is little doubt that further observations will result in its being found in the majority of water supplies, therefore it is of some interest to determine whether it possesses any pathogenic significance. Morphologically it is impossible to distinguish the common water leptospiira from *L. icterohaemorrhagiae*, although, perhaps, too much importance should not be attached to such a resemblance in organisms presenting so few morphological characters. On the other hand, there is a biological relationship between them, for agglutination of a leptospiira from London tap water was produced by a 1 in 40 dilution of an anti-leptospiira serum, prepared at the Wellcome Physiological Laboratories for a virulent strain of these organisms, isolated by Buchanan. For the supply of this serum I am indebted to my friend Dr. Okell, who had used it in his researches on jaundice in dogs.

If we turn our attention to the history of recent outbreaks of spirochaetral jaundice it is obvious that there must be some very widespread source of infection in nature, for it is impossible to explain the origin of the cases in any other way. Certain outbreaks, notably that in Edinburgh described by Lyon and Buchanan,⁴ have been traced to human carriers of the infection, and once the disease becomes established in man it seems to be contagious, especially among children. The exact mechanism of transmission in such cases is not obvious, but presumably the infection is conveyed by the urine, which often contains living leptospiira. No such explanation, however, can be offered for the origin of most outbreaks, which generally seem to be associated with conditions that would favour the saprophytic growth of leptospiira.

The best example of this nature is the outbreak in East Lothian, described by Buchanan,³ who was able to show that certain coal mines were the source of infection. In the infected mines typical *L. icterohaemorrhagiae* were obtained from the slime on the roof, in situations that appeared inaccessible to rats. Moreover, the inoculation of this slime into guinea-pigs produced the characteristic symptoms of spirochaetral jaundice, to which the animals succumbed, and abundant leptospiiral organisms were present in all their organs.

On the Continent various epidemics have been traced to insanitary bathing establishments, amongst which may be mentioned the outbreak near Magdeburg described by Kornei,⁵ which was arrested by closing certain bathing sheds. The Vesle outbreaks in Northern France were traced to the river, and leptospiiral organisms were found by Etiegeon⁶ in the river water and mud. During the great war epidemics of the disease occurred in wet ill drained trenches, where conditions, especially in dug outs, would undoubtedly favour the growth of leptospiira.

The disease has also been recorded from among workers in sewers, or, in one or two cases, in persons who had fallen into filthy water.

The best example of such a case is that described by Manson-Bahr⁷ of a seaman who fell into the Thames off Gravesend, and was nearly drowned. Five days later he developed a typical attack of spirochaetral jaundice, and

Wenyon and Brown, who made a laboratory examination of this case, were able to recover the leptospiira from guinea pigs inoculated with the patient's blood. A subsequent examination, recorded in the earlier part of this paper, supports Dr. Manson-Bahr's view that the infection had originated from immersion in contaminated water, for I found the Thames water at Gravesend to contain as many as one leptospiira in every 40 fields of the microscope.

The work of Zuelzer⁸ and others on water leptospiira shows that non-pathogenic forms may acquire pathogenic properties after prolonged culture, although Buchanan³ is the only observer who has succeeded in finding virulent leptospiira living saprophytically in nature.

The occurrence of a similar infection in wild rats, in which the organism can exist as a harmless commensal, has led to the view that they may serve as a reservoir, and in view of the usual habitat of these animals it seems reasonable to assume that they acquire the infection by drinking filthy water containing leptospiira. The observations of Foulerton,⁹ Stevenson,¹⁰ and Balfour¹¹ show that a considerable proportion of London rats are infected with the disease, Balfour¹¹ finding leptospiira in 22.6 per cent of 154 brown rats. Since the organisms are passed out in the urine, these animals may serve to spread the infection, but their agency is not essential, as outbreaks have occurred in which their presence was definitely excluded.

Considering all the known facts concerning outbreaks of spirochaetral jaundice, there is reasonable evidence for the assumption that certain strains of water leptospiira may acquire pathogenic properties, and therefore constitute a potential source of human infection. The conditions under which they acquire such properties are not clear, but one important factor is the dose, as the results of inoculation experiments with the water leptospiira, as well as with blood spirochaetes, have shown that it is necessary to introduce a minimal number of organisms in order to produce infection. For example, Buchanan³ failed to infect guinea-pigs by the inoculation of 1 c.c. of slime containing leptospiira, but with four times this amount produced fatal infections. On the other hand, the occurrence of laboratory infections among experienced bacteriologists, who have worked with this disease in guinea pigs, suggests that after passage through these animals the virulence for man is considerably increased, and it is possible that similar variations may occur in nature.

The susceptibility of the host is another important factor, for the inoculation of identically the same dose into a number of guinea-pigs produces very different results, ranging from a complete absence of any obvious effects up to the development of a fatal attack of intense haemorrhagic jaundice. Probably the human host is equally variable in susceptibility to infection, and it is a noteworthy feature that most of the recent outbreaks of the disease have been confined to children or young adults.

The presence of leptospiira in water in small numbers is obviously harmless, otherwise a considerable proportion of the population would be affected, but under insanitary conditions, and especially when faecal contamination of the water takes place, the organism may increase in numbers and constitute a real source of danger. Under modern sanitary conditions there is little likelihood of the disease assuming any great importance, but under abnormal conditions, such as war, or in countries where sanitation has not yet developed, the infection is likely to continue, as the causative agent is evidently capable of living indefinitely as a saprophyte, either in water or in damp localities containing suitable organic matter. Spirochaetral jaundice may be added, therefore, to the long list of diseases which owe their origin to insanitary conditions and lack of attention to public hygiene.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

REMOVAL OF AN OVARIAN CYST IN AN AGED WOMAN RICHMOND

15 November, 1923, I was asked by a colleague to tap an ovarian cyst. The patient was an old lady who had previously refused operation for various reasons. The necessity for tapping became more and more frequent, and on each occasion from 16 to 18 pints of thick glaucous fluid were drawn off. The last interval between paracenteses was three weeks. The old lady declared that her life was not worth living with the continuous discomfort of pressure symptoms, and said she would rather be operated on and die under the anæsthetic than endure it any longer. After a lengthy discussion with the patient's doctor I decided to take the risk and make an attempt at permanent relief. I said that if I could not remove the tumour in its entirety in a given time I would not proceed further with the operation. My only fear was that it might be malignant. I tapped the cyst for the last time on May 3rd, and operated exactly one week later.

The operation was performed on May 10th, when the patient was 90 years of age. The usual midline incision was made, and I found a large multilocular ovarian cyst with multiple adhesions to the peritoneum, but fortunately these could easily be broken down by the hand and did not require ligature. The pedicle was clamped, ligatured, and the cyst removed whole. It was not malignant, and contained over a gallon of fluid. The operation took twenty-five minutes.

The patient sat up in a chair on the seventeenth day, and walked from one room to another on the twenty-second day. To use a familiar and unscientific expression, "she did not turn a hair," and continues to enjoy good health. This case may not constitute a record, but it is sufficiently unusual to warrant publication.

SEVERE GENERALIZED DERMATITIS AFTER A LOCAL SCALD

The case of severe dermatitis following ultra violet light reported by Drs. MacCormac and McCler (April 11th, p. 695) is interesting and instructive. Recently I had a case presenting many points in common, but caused by scalding. A lady, aged 55, scalded one foot and instep (probably a scald of the second degree), which was treated rather casually with home remedies, no doctor was called in, and no serious attempt was made to keep the part aseptic. Putrid healing occurred after some months, but then the condition became worse and spread over the body. When I first saw her, three months after the accident, the affected foot was acutely inflamed and there were extensive raw areas—copiously weeping. The other foot was similarly but less severely affected. There was a generalized acute eczematous dermatitis all over the chest, trunk, legs, and arms, with considerable pruritus, the face alone escaped. In ten days, with aseptic treatment of the foot and soothing applications to the rest of the body, and mistura alba, the condition completely cleared up. There was no previous history of eczema, no doubt the generalized dermatitis was produced by toxic absorption from the scalded foot.

A NOVEL METHOD OF REDUCING A DISLOCATION OF THE ELBOW

A BRITISH sailor came into the Cottage Hospital at Algiers recently with a typical dislocation of the right elbow, the forearm being displaced forwards. It so happened that Professor Curtillet, surgeon to the Civil Hospital, was in the

hospital—a circumstance which enabled me to watch the reduction of the displacement by what appeared to me to be a novel method.

Standing on the right side of the patient, who was in the erect position, he grasped the patient's right arm firmly above the elbow with both hands, leaving the forearm free. Having raised the limb to an obtuse angle with the trunk he then, suddenly, taking the patient quite by surprise, imparted to the limb a violent flail-like movement, whereupon the displaced forearm slipped back into its place. The pain was no doubt considerable, indeed, the patient collapsed and fell to the ground, but it was only momentary, for he got up smiling. Dr. Curtillet told me he had employed this method many times with invariable success, and it is so simple that it deserves to be more commonly known.

Alger.

ALFRED S. GLENN

PLUGGING THE POSTERIOR NARES

The customary method of plugging the posterior nares in epistaxis by the use of a catheter or of Belloq's sound has several disadvantages. The use of a forehead mirror is almost essential, and, when the hæmorrhage is severe, it may be impossible even to see the thread. In a case where the Belloq sound failed the following method was successful.

One end of a piece of packing tape was twisted several times round the tip of the forefinger, which was put into the mouth and pushed up behind the palate into the nasopharynx. With snare forceps introduced through the nose the tape was then easily seized and drawn out through the anterior nares. A roll of gauze was attached and secured in position in the usual manner.

This method, being carried out by the sense of touch alone, can be employed where a suitable light is not available, or where the view of the pharynx is obscured by blood. In such circumstances the method, which I believe to be new, may prove useful.

HENRY S. RUSSELL, B.Sc., M.B., Ch.B.,
Barrow-in-Furness. Head Surgeon North London Hospital.

FACIAL FISTULA OF THE SCROTUM

The case here recorded was shown to the Sierra Leone Branch of the British Medical Association as an interesting case, showing the vitality and resistance to sepsis of some of the natives.

A man aged about 46 was admitted to the Connaught Hospital, Freetown, Sierra Leone, on November 22nd 1924 complaining of a wound in the leg. He was found also to have a facial fistula of the scrotum with a large right inguinal hernia in a much enlarged scrotum. The opening was about three quarters of an inch in diameter and could be probed to a depth of two inches. The patient stated that about eighteen months previously he had been stabbed with a knife while at work on his farm, but there is a suspicion that the wound was inflicted while engaged in burghling as he was known to be a burglar. Very seldom had he used rectum or anus since that time. All faeces passing by the fistula.

An operation was performed by Dr. J. Y. Wood of the West African Medical Staff assisted by Dr. E. J. Wright and the writer.

As there did not appear to be much adhesion at the external ring an incision two inches long was made just below this with a view to cutting across the loop making an end to end anastomosis and performing a radical cure for hernia. This was found to be impossible owing to adhesion and the wound was closed. A fresh incision was then made above the fistula and enclosing the latter elliptically. The bowel proved to be the cæcum much dilated and not a double loop. One side was embedded in a dense mass of hard fibrous tissues from which it could not be freed. It was found possible however, by careful dissection to free the sac below the mass. The base of the fistula was then cut across by a second elliptical incision—the edge in the fibrous mass being freed sufficiently to catch it with stitches. A row of continuous sutures closed the aperture about two inches long in the bowel. A second row stitched down a fold of the outer coats over this. A third row of interrupted sutures massed the sac over this and the wound in the scrotum was closed. The wound healed by first intention the first dressing not being removed for ten days during which time the patient remained on fluid diet. On the third day after operation the bowels acted naturally and continued to do so, a purge being given on the tenth day. He was discharged on the eighteenth day completely cured but still with a scrotal hernia. The scrotum at the site of the operation was soft and pliable and the fibrous mass had practically disappeared.

W. F. OUMIRI, TUTOR
Connaught Hospital, Freetown, Sierra Leone.

AN INDIGINOUS OPERATION FOR STRANGULATED HERNIA

Medicine is to some extent spread throughout Mohammedan communities in Northern Nigeria. The physician is the *malam*, or learned man, and the main part of his practice consists in selling amulets and prescribing draughts of water in which are dissolved the ink used to write a sentence of the Koran. The surgeon, represented by the *haiber*, deals with abscesses and wounds, and cures, while the greater part of his work is very crude, it is often founded on sound common sense and occasionally has quite brilliant results, as evidenced in the following case.

Yesufu a Hausa native of Kano province aged about 40 consulted me with regard to a faecal fistula. He said that three years ago a swelling which had come down into his scrotum for a long time and disappeared when he lay down became suddenly larger and refused to disappear. It gave him great pain and he vomited. The village practitioner who treated all acute swellings thus with good results—heated in narrow head until red hot and plunged it into the swelling causing black water to come out and then in a short time faces the pain disappeared and the patient was well but all his motions now came out from the opening which had never closed. He was well nourished and healthy looking. On the anterior surface of the scrotum just below and to the right of the root of the penis, was an opening from which semi solid faeces were propelled intermittently. Nothing but a small amount of mucus was ever discharged from the anus. I thought it better to see if any obstruction existed internally before closing the fistula. On opening the abdomen the transverse colon was found to be the portion of bowel implicated in the hernia, while coils of bowel consisting of terminal ileum caecum ascending colon and transverse colon were adherent in the right iliac fossa. The adhesions could not be undone so the appendix having been removed an anastomosis was made between the entering loop of colon which was thus and atrophic. Following this operation faeces passed both by the fistula and by the anus. Twelve days later, on the day before the fistula was to be closed the temperature relapsed fever developed—not an unusual complication in the wards at present and impossible to eradicate under existing epidemic conditions the blood was crowded with large spirochaetes but they rapidly fell as did the temperature, after intravenous injection of neo-harsivan.

Under spinal anaesthesia the inguinal canal was opened and the bowel freed from adhesions to the peritoneal sac which was very thick, the fistula was excised and the bowel closed and returned to the abdomen. The sac being dealt with the inguinal canal was obliterated after excising the testicle and cord conditions for repair being unfavourable. No further complications occurred and the patient was discharged with the bowels acting by the proper route.

As an emergency procedure with the facilities available the indigenous operation was undoubtedly excellent and probably saved the man's life.

PEDIATRICS

THE provincial meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine took place at Cambridge on June 20th. By kind permission of Professor Hopkins the meeting was held in the Sir William Dunn Laboratory of Biochemistry, the chair was taken by the President, Dr H C CAMERON.

Bone Formation and Rickets

A discussion on the biochemistry of bone formation and the application of this to the pathology of rickets was opened by Dr H D KAY, who briefly stated and criticized the various theories of the biochemical mechanism of the deposition of bone in normal animals which have been advanced by Pfaundler, Pauli and Samco, Freudenberg and Georgy, and particularly by Robinson and his collaborators. The central discoveries on which new ideas of the mechanism of bone formation depended were (1) that the cells of ossifying cartilage, and to a less extent those of full-grown bone, contained a powerful phosphoric esterase which decomposed most phosphoric esters readily, and (2) that there was a phosphoric ester present in blood upon which this enzyme acted, resulting in the liberation of phosphate ions in the immediate neighbourhood of the site of ossification. Tertiary calcium phosphate (or possibly some compound of even greater lability) was laid down because of the local increase in the concentration of PO_4^{3-} ions brought about by the enzyme led to the solubility product

of $Ca_3(PO_4)_2$ (or that of the more basic compound) being exceeded. The evidence on which this modern view rested was critically examined, and it was found to explain many of the facts. Rickets, however, was not necessarily associated with a shortage either in the enzyme activity of the bone, or in the amount of phosphoric ester in the blood, which was hydrolysable by the bone enzyme. Dr H W C VINES suggested that in the light of Dr Robison's discovery of a phosphoric ester in ossifying cartilage, the deposition of calcium salts might be carried out according to the equations—

1 $CaR + 2H_3PO_4 \rightarrow CaH_2(PO_4)_2 + H_2R$
2 $19CaH_2(PO_4)_2 + 52NaHCO_3 \rightarrow [Ca(HCO_3)_2 \cdot 6Ca_3(PO_4)_2] + 26Na_2HPO_4 + 52H_2O + CO$

The double salt could be prepared by the neutralization of a solution of $CaH_2(PO_4)_2$ by $NaHCO_3$. Phosphoric acid or dried calcium phosphate dissolved this salt molecularly with the formation of $CaHPO_4$. Taking the view that the Ca and P equilibrium of the plasma was directly dependent upon the skeletal Ca salts through the agency of $CaHPO_4$, it was shown that buffered protein solutions to which solid $CaHPO_4$ was added in certain concentrations came into an equilibrium, in which the percentage Ca content was about 12 mg, and the PO_4 10 mg, the pH being constant at pH 7.4. From this a graph was built up indicating the probable conditions in the plasma. It was shown that a very slight decrease in the plasma PO_4 concentration would cause a fall in Ca to below 7.5 mg per cent. This would be compatible with tetanic rickets with low Ca and normal phosphorus. A further decrease in PO_4 to 50 per cent of the normal value would lead to a Ca value of 9 mg per cent, indicating perhaps a rachitis with normal calcium and low phosphorus. Any further decrease in P_2O_5 would lead to a lowering of Ca. From these experiments Dr Vines suggested that rickets might be associated primarily with an error in phosphorus metabolism, and that the calcium metabolism was affected secondarily. A discussion followed in which many speakers took part, and in which the decrease of the grosser forms of rickets during the last few years was emphasized, and the great variety of satisfactory methods of cure was illustrated.

Pulmonary Lesions due to the *Pneumococcus*

Dr J F GASKELL described certain experiments on which he had been engaged in an endeavour to elucidate the origin and relationships of the various forms of pulmonary lesions produced by the pneumococcus. Rabbits were used for the experiments, and he claimed that a close parallel existed between the lesions obtained and the various forms met with in children. All experiments had been made with a single strain of pneumococcus type I, which had been obtained from a fatal human case. The virulence of the strain was varied at will, and could be controlled and measured with sufficient accuracy by the minimal lethal dose to mice of saline dilutions of the way being expressed as the titre. With low titres no lesions were obtained in the lung, with titres between 3 and 4 either central round the main bronchus or more diffuse. With titres between 4 and 5 the lesions were larger and became lobular in type, with titres between 5 and 6 either lobular consolidation was produced or the lung lesions, though diffuse, were incomplete, and were accompanied by double pleurisy with much purulent effusion, and often also by pericarditis. To produce the lobular lesion the dose must be small. With titres of 6 and over a septicaemic condition was produced, with intense invasion of the blood stream and characteristic sero-haemorrhagic effusion in all lobes, very mild, a positive blood culture could not be obtained from the heart's blood in the first three days. Evidence was given that with the lower titres the condition was a bacteraemia rather than a septicaemia, and the theory was advanced that the organisms present in the blood were always within the leucocytes and not free. Dr Gaskell suggested that the size of the lung was of importance in the production of the lobular lesion, and that the larger

lung of adults gave a longer period for the defensive mechanisms to concentrate, and thus prevent the involvement of the pleura, while in children the periphery of the lung was reached by the spreading infection much more rapidly, and thus empyema was common and lobular pneumonia comparatively rare.

After the meeting a dinner was held in Christ's College, by kind permission of the Master and Fellows.

TROPICAL MEDICINE

The annual general meeting of the Royal Society of Tropical Medicine and Hygiene was held at 11, Chandos Street, Cavendish Square, on June 18th. The retiring President, Surgeon Rear-Admiral Sir Percy Bassett-Smith, handed over the badge of office to the newly elected President, Dr ANDREW BALFOUR, who, in taking the chair, reviewed the activities and growth of the society during the two years' presidency of Sir Percy Bassett-Smith. The Chalmers Memorial Gold Medal, which is given biennially to persons under 45 years of age for "researches of outstanding merit contributing to our knowledge of tropical medicine and hygiene," was presented by the new President to Professor Warrington Yorke of the Liverpool School of Tropical Medicine, in recognition of his work on trypanosomiasis, malaria, and many other subjects.

Observations on Malaria during Treatment of General Paralysis

Professor WARRINGTON YORKE read a paper on "Further observations on malaria made during treatment of general paralysis," a previous communication on the same subject having been made by him in conjunction with Dr J. W. Scott Macfie last year. They had noted that induced malaria, whether as a result of direct inoculation of the blood of an infected patient or the bites of infected mosquitos, was remarkably susceptible to the action of quinine in a dosage of 30 grains on three consecutive days. It was further discovered that quinine has no true prophylactic action, for in the case of patients bitten by infected mosquitos daily doses of 10 grains of quinine, administered for five days before, on the day of, and for seven days after, the infecting bite of the mosquito did not prevent the onset of typical malaria. Similarly, 30 grains given on the day of the bite and on each of the two succeeding days did not prevent malaria. From these results it was evident that quinine, though very efficacious for the primary attack of malaria when parasites appeared in the blood, had no action on the sporozoites injected by the mosquitos. The communication made by Professor Yorke dealt with the subsequent history of the cases reported upon last year. Of the cases, which numbered over a hundred, of malaria induced by the inoculation of virulent blood and treated by the three-day course of quinine from one and a half to two and a half years ago, the number of relapses had remained at 2 per cent. The inoculation of the strain from man to man during three years, involving more than forty passages, had not produced an increase in virulence or any morphological variation in the parasite itself. Turning to the infections induced by the bites of mosquitos and treated like the series just mentioned, the more prolonged observations showed that 21 of the 37 patients relapsed. Of these 2 relapsed in the first month, 2 in the second, 1 in the third, and the rest from the fourth to the eleventh months. The late development of these relapses was in marked contrast to the experience of the war, when the vast majority of relapses occurred within one to one and a half months of cessation of treatment. Of the 21 relapses, in the majority of cases fever disappeared either spontaneously or as a result of a second short course of quinine. These results were very different from those obtained during the war. It did not appear that the amount of quinine or the manner of its administration, the period of the year when infection or treatment occurred, or the strain of parasite, could explain this outstanding difference. The only factor which could reasonably account for it was the individuality of the patient. This factor appeared to be the one which determined whether a relapse would occur and if so when.

On the subject of the mechanism of the action of quinine Professor Yorke could see no reason to alter the opinion expressed in the communication made last year. Quinine destroyed large numbers of the malarial parasite, the halcyon bodies of which acted as an antigen to stimulate the production of antibodies which, if present in sufficient amount, brought about a sterilization of the infective and the cure of the patient. As to the immediate action of quinine in destroying parasites, some evidence had been obtained that the drug, acting indirectly, certain bodies co-operating with the quinine in producing a substance directly toxic to the parasite. The use of large doses of prolonged courses of quinine was not advocated. On the other hand, the best method of treating malaria was to deal with the attack with a few moderate-sized doses as it arose, and if relapses occurred the treatment should be repeated, the general health should be maintained by diet and the avoidance of exhaustion, for relapse was directly related to the reaction of the patient himself and his capacity to develop immune body.

CHLOROFORM ANAESTHESIA

A meeting of the Anaesthetic Section of the Royal Society of Medicine was held in the University Buildings at Manchester on June 27th.

Dr H. P. FAIRHURST (Glasgow) opened a discussion on chloroform anaesthesia. At a time when chloroform was being subjected to criticism as an anaesthetic, even to the extent of protesting altogether against its use, he thought it proper that its legitimate uses should be discussed since a considerable amount of space in textbooks was devoted to the teaching of its exhibition as an anaesthetic. The fact that people talked of an ideal anaesthetic seemed to indicate that no ideal anaesthetic had as yet been discovered. On the other hand, Professor Hobday considered chloroform the ideal anaesthetic for animals. Ether was the most formidable rival of chloroform, and it certainly had its proper place as an anaesthetic, though it was not supreme. It was productive of fatigue, its stimulative action on the circulation left the patient in a condition of reaction at a moment when stimulation was most needed, and the subsequent fall of blood pressure was the cause of many post-operative fatalities. Dr Fairhurst thought too much emphasis was laid on the condition of the patient during operation, and the after-effects were ignored. Statistics were misleading, as they included many personal factors, such as variations in skill of different anaesthetists and variations in the condition of the patients prior to operation. Chloroform should not be the choice of the occasional anaesthetist, but the expert would not have more fatalities with it than with ether. Desirable surgical conditions were more easily reached with chloroform than with ether, while in the post-anaesthetic stage the blood pressure tended to rise and would respond to stimulation. At the time of operation there was less tendency to bleeding, and afterwards the chances of lung complication were fewer. As offsets to these advantages there was certainly the danger of acidosis and chloroform syncope. It was usual to classify syncope as of two kinds—sudden and gradual. There was, however, no vital distinction between the two. They were of the same nature, differing only in rapidity of onset. In the sudden variety the time available for remedial measures was less. It was rarely necessary to do more than control the circulation by putting the patient in the Trendelenburg position if the condition were recognized at the onset. Lary considered ventricular fibrillation the result of light chloroform anaesthesia rather than overdosage. The suprarenal glands were stimulated, and the result was fibrillation. As the result of clinical experience the speaker did not agree with the overdosage theory, whereas the alternative theory of vagus inhibition appealed to him. He said he practised light dosage with a Veinon-Harcourt apparatus up to 3 or 3½ per cent of vapour strength, the bottle being immersed in hot water to increase the percentage and keep it uniform. Atropine gr. 1/100 was given to adults, and in smaller doses to children. In the later stages of anaesthesia deficient oxygenation was combated by oxygen inhalations, and in deep abdominal cases was given through out. Sepsis in the abdominal cavity ruled out chloroform.

In conclusion, he quoted Willet, who stated that if he had to be operated upon and the anaesthetist was unknown to him he would choose chloroform for the anaesthetic, but if he had a warning, and could choose his anaesthetist he would prefer chloroform.

Dr J. BLOMFIELD (London) said it was difficult to criticize a paper which was so eminently rational, and he only differed from the opener on one point. There were certainly two kinds of chloroform syncope, and from clinical experience he concluded that there were deaths due to overdosage and deaths without overdosage. He had seen a man die in the early stages of chloroform anaesthesia, the administration being conducted by a competent anaesthetist, the corneal reflex still brisk, there being no evidence of overdosage, no high concentration of the drug, no deep anaesthesia, the patient sitting up in his struggles, when he suddenly fell back and died.

Dr S. R. WILSON (Manchester) agreed with the opener on many points, but he disputed Professor Hobday's dictum regarding chloroform as the ideal anaesthetic for animals. It was the regular thing for two out of every ten or twelve dogs anaesthetized with chloroform to die, whereas he himself had not lost a single dog in the past five years when giving ether. Veterinary anaesthesia was in the same position to-day as that of human anaesthesia twenty years ago. He agreed with Dr Blomfield that there were two types of chloroform syncope. If vagus control had any importance, why give atropine as a routine measure?

Dr W. J. McCANN (Birmingham) believed that a C.E. mixture varying in proportions with the type of case was the nearest approach to the ideal anaesthetic. When giving chloroform sufficient was not done to ward off its dangers. The patient should have preliminary preparation with brandy, strychnine, atropine, digitaline, and pituitum. Ether was given for too long at a time, and 17 hours deep ether anaesthesia was enough for anyone. In certain operations a mixture was essential—for example, in operations on children on the eye in brain, mastoid, Gasserian ganglion, and lung operations.

Dr G. R. PHILLIPS (London) called attention to the construction of the Vernon Harcourt inhaler in which a special apparatus was provided to increase concentration up to 41 per cent, without heat. The percentage of chloroform used was uncertain when heat was used. Dr C. P. THOMAS (Birmingham) advocated the routine lowering of the head a few inches as a precaution against heart failure when using chloroform, especially in gynaecological cases.

Dr ALEXANDER WILSON (Manchester) said that he had met with two patients who died on the table before any anaesthetic had been administered. The patients died from circulatory failure precisely similar to that which occurred after severe haemorrhage. The symptoms were pillor and dilatation of the pupil, with convulsions in some cases. Artificial respiration should be commenced at once, and the head of the table lowered. Overdose occurred in two conditions. In one there was violent struggling, with consequent deep inhalations and subsequent overdose. In the other the patient was gradually over-osed, even with small amounts, as the result of respiratory obstruction. In the first, death was due to cardiac paralysis, resulting from over-excitation, and not really to chloroform. Again, from over-excitation, so common in the past, might be a contributory cause.

Dr FETTERSTONE (Birmingham) said that he must have clear reasons for so doing before giving chloroform, for once the drug had been absorbed it was well-nigh impossible to get it out of the system quickly. Light anaesthesia at the beginning of operation was dangerous, and there was also a danger of collapse later, in children, when they had been returned to bed. Moreover, with chloroform there was a fall in the systolic pressure during administration, accompanied by a rise in the diastolic pressure. Thus the weak pulse was hampered, not only by a falling output of the heart, but also by increased peripheral resistance. Nervous patients should never be given chloroform, for fear of collapse.

On the conclusion of the discussion, a demonstration was given in the physiological laboratory by Drs S. R.

WILSON and B. McSWINEY of the effects of adrenalectomy injections during chloroform and ether anaesthesia on a dog. An exhibition was also arranged of physiological methods of investigating acidosis, and a new anaesthetic apparatus was also on view.

TUBAL PREGNANCY

At the last meeting of the North of England Obstetrical and Gynaecological Society, held at Leeds, with Dr J. L. GYMILL, President, in the chair, Dr E. O. CROFT (Leeds) recorded several cases of tubal pregnancy recently operated on by him presenting somewhat unusual symptoms.

1 The first patient a married woman aged 39 whose only child was born ten years ago had menstruated regularly until June, 1924. This period was prolonged to seven days and on the seventh day she had a sudden violent pain in the left groin passing through to the rectum colicky in nature which lasted twelve hours. Two shorter similar attacks of pain followed at intervals of six hours and vaginal bleeding continued for a week. She then had, during the following six months varying slight attacks of pain, with menstrual periods regular though increased in amount. She was admitted to hospital on January 17th 1925 when there was rigidity in the left lower quadrant of the abdomen and on vaginal examination a small swelling in the left tubo-ovarian region was felt. At operation a small dark round mass was discovered in the tube and on handling this the tube broke across just proximal to the side of this lump. Beyond it the tube appeared normal. The entire tube was excised. The points of intratubal bleeding and mole formation remaining for six months with return of menstruation and the small size of the mole contained in a small portion of the tube the rest of which was normal. The length of time the mole had been retained must have accounted for the lack of microscopic evidence of villi on examination of it.

2 The second patient was aged 42 had four children (the youngest born five years previously) and had had left salpingo-oophorectomy for tubo-ovarian abscess fourteen years previously. The points of interest in this case in addition to the previous operation were the absence of amenorrhoea and the large amount of evidence of old inflammatory disease around the tubal mole and there was no history of any acute symptoms.

3 This case was that of a married woman aged 29 who had had one child and one abortion. She was admitted to hospital in June 1924. She had slight loss and slight pain for a day or two and then three days before admission a severe flooding which subsided. On the day of admission she had severe pain and was very blanched and suffering severely from shock. At operation the right tube was much enlarged and there was a large quantity of free blood in the peritoneal cavity. The tube was removed and later after hardening was opened and found to contain a perfect ovum with embryo in its amniotic cavity. The points of interest were the absence of amenorrhoea no mole formation (ovum intact), and profuse haemorrhage from the open end of the tube.

4 This patient aged 31 was married and had two children the second born six years previously. She began to lose on January 18th 1925 the date her normal period was due but she only had slight aching pain in the abdomen never on acute attack. Vaginal examination revealed the uterus displaced forwards by a tender swelling in the pouch of Douglas. At operation much dark tarry blood was found in the peritoneum with the right tube ruptured and containing much clot. Haemorrhage there was no amenorrhoea but two months continuous loss and an absence of any acute attack of pain in spite of a severe rupture of the tube and intraperitoneal haemorrhage.

5 The interest of this case was that after a series of six abortions none of which went beyond six weeks the patient had a tubal pregnancy and the later history resembled more that described in textbooks seven weeks amenorrhoea with sudden attack of pain and slight loss followed by severe pain and free bleeding.

6 This patient had two years sterility following marriage and then on July 16th 1924 a month after a normal period had severe pain in the left lower abdomen and a week later slight bleeding which continued for three weeks to the date of admission. For three days before admission she had severe pain and at the operation a large amount of intraperitoneal haemorrhage was found with a mole still present in the left tube. The points of interest were two years sterility and pain at the date of the expected period but no show until a week later.

In recording these cases Dr Croft drew attention to the unusual points, indicating how the usually recognized symptoms and signs were only exceptionally present in any one case, and endeavoured to show that early symptoms, if seriously noted, would more often lead to earlier treatment before an acute catastrophe took place.

Treatment of Incision of the Uterus
Mr W. W. KING (Sheffield) read notes of a case of incision of the uterus replaced by a new form of Aveling repositors. The case was of interest because of the slight

trauma which apparently began the process, and the case with which the inverted uterus was replaced by his modification of Aveling's repositor three weeks after the accident.

The patient, aged 27, was delivered spontaneously of her first child on March 1st, 1925. A slightly abnormal amount of haemorrhage during the second stage caused her medical attendant to put his hand into the vagina for the purpose of removing the placenta from the uterus. The placenta was, however, mainly in the vagina and came away without any difficulty. Serious collapse and vomiting followed immediately, but no further haemorrhage. Inversion was thought of but the absence of haemorrhage and an external tumour were taken by him to negative the diagnosis. The shock passed off, and the puerperium was afebrile and on the eighteenth day a routine pelvic examination was made. This disclosed a rounded tumour in the vagina which was recognized as an inversion. Mr. King saw her the same day when she looked and felt perfectly well. The inverted uterus was the size of a cricket ball in the vagina. She was admitted to hospital and after a few days' treatment with glycerin the modified Aveling's repositor was inserted and the uterus was completely reinserted in six hours, with very little pain or discomfort. Recovery was uninterrupted.

The instrument, as modified by Mr. King, made it possible to get the point from which traction was made as close to the vulva as possible, and so diminish the liability to lateral displacement, secondly to supply a ready means of adapting the shape to that of the vagina, and thirdly, a gauge is provided by which the process of reinsertion could be noted without removing the apparatus.

The stem was of copper and could be bent to fit the curve of the vagina and so transmit pressure in the correct axis. Before fitting the apparatus a small piece of strapping placed on the stem should indicate the position the plate would occupy when the fundus had been reinserted to a point at or about the cervix. The plate from which traction was made was rectangular measuring 6 by 3 cm. and could be fixed at any position on the stem by means of a set screw. The corners of the plate were drilled to take the ordinary circular elastic bands supplied in stations. When these bands were looped into the holes and attached to a suitable belt and extended by about 2.5 cm. the right amount of pressure was produced. Attached at first half an inch from the vulva and readjusted as reinsertion took place, the prearranged point indicated above would be reached. The cup used was of the ordinary type till the fundus had been replaced to the level of the cervix and then the instrument was withdrawn and the cup replaced by a smaller cylindrical one which could easily pass through the cervix. After reinsertion this cup could be withdrawn with great ease and no pain.

The President congratulated Mr. King on the instrument and its successful use. Dr. Croft thought the original Aveling repositor was conical at the lower end, and so its removal was easy.

Puerperal General Peritonitis

Dr. CARLTON OLDFIELD (Leeds) read notes of two cases of puerperal general peritonitis. At the outset he referred to a short paper, contributed by himself to the Society two years previously, on twelve cases operated on, with seven recoveries. His main reason for returning to the subject was that the statistics of the recent investigation of puerperal infections proved two things that general peritonitis was very common, and that the treatment of it was by no means successful.

The first patient had a spontaneous delivery on January 30th, 1925, the only interference being rupture of the membranes by the midwife when they were bulging at the vulva. On the sixth day after delivery—sixteen hours after the onset of severe pain—she was admitted into the Leeds Infirmary with temperature 99.8° F., pulse 108 and the abdomen rigid and tender, not moving on respiration. Laparotomy allowed large quantities of yellowish foul-smelling liquid to escape from the peritoneal cavity. The appendix and right tube were normal, the left tube red and inflamed. Left salpingectomy was performed with drainage of the abdomen. Examination of this tube showed it acutely inflamed, no organisms were grown from the fluid removed. The patient made a good recovery.

The second patient was 31 years old and had four children. She had a profuse purulent vaginal discharge during pregnancy, normal labour on December 29th, 1924. One hour after delivery the temperature was 103° F. and pulse 120. Pyrexia persisted with rigors on the second, fourth, fifth and sixth days after delivery. On January 4th, 1925, the temperature was 104° F., pulse 135, she had severe abdominal pains, diarrhoea and occasional vomiting, and the abdomen was distended. She was operated on the next day, and a large quantity of sero-purulent fluid evacuated. The left tube which was swollen and congested was removed and drainage tubes put in the pelvis. She died on January 9th of general peritonitis. Streptococci were grown from the fluid.

Dr. Oldfield thought it desirable that in cases of puerperal infection a sharp lookout should be kept for

evidence of general peritonitis, and the abdomen should be opened as soon as the condition had been diagnosed. His experience of fourteen cases (with eight recoveries) appeared to show that the death rate from puerperal peritonitis could be considerably reduced by operative treatment on the lines adopted by surgeons in treating general peritonitis.

Breech Presentation and Ectopic Pregnancy

Dr. GORDON FITZGERALD (Manchester) read notes of a case in which a breech presentation was complicated by an extrauterine pregnancy.

The patient, a 4 para, aged 32, was admitted to hospital in labour the breech presenting. Previous labour had been without difficulty and so none was anticipated here. During the second stage there was considerable delay, and on examination a mass was found in front of the breech which resembled a cervical lip, supported by the presenting part. The swelling was soft and bluish and the efforts made to push it up were unsuccessful. After some further delay the mass ruptured and there was much haemorrhage, and then the labour was terminated fairly quickly. The uterus contracted well following a slight further haemorrhage. Two days later, after a recurrence of haemorrhage, Dr. FitzGerald examined her and was surprised to find the examining finger pass more easily through an opening in the posterior fornix than up towards the cervix. Under an anaesthetic a cavity filled with blood clot lying in the left broad ligament was found. From the cavity recent and old blood clot was removed and also a small embryo about an inch in length. The cavity was briefly packed with gauze which was removed in twenty-four hours, and the puerperium was otherwise uneventful.

No indication was obtained from the patient's history as to when the extrauterine pregnancy ruptured through, or was aborted from, the tube. Accepting the view that ovulation ceases during pregnancy, this (two months' embryo) must have remained about eight lunar months unabsorbed.

Uterine and Ovarian Tumours

Mr. W. GOUGH (Leeds) described two cases of sarcomas of the uterus.

The first patient, aged 66, had her last pregnancy twenty-three years ago, menopause ten years ago. There was a history of three months' vaginal haemorrhage, but no pain. Exploration with a curette produced rounded compressed nodules, the colour of milk chocolate, which on examination showed sarcoma of a mixed cell type. Vaginal hysterectomy was done and the uterus examined later had the pedicle of the polypoid growth still present on the posterior wall half an inch from the fundus.

The second patient, aged 59, had one child thirty years ago and ever since the menopause eight years ago had suffered from discharge with occasional bleeding. Examination revealed a hard rounded central tumour extending to two inches above the umbilicus and a large polypus with sloughy surface filled the vagina. At operation the polypus broke into fragments with suspicious case and a large quantity of greyish stringy growth was removed from the uterine cavity. Microscopical examination showed a rounded cell sarcoma. Abdominal parasthysterectomy was performed. On opening the specimen the fundus was found to contain a fibroid as large as a tangerine orange, below this was a large cavity with foul sloughy nodular walls from which the growth had been excavated at the first operation.

The second case might have been one of so-called sarcomatous degeneration of a fibroid, but Mr. Gough held that this did not occur, for he had never seen a section showing definitely this change.

Dr. CARLTON OLDFIELD showed a specimen of a growth about the size of a walnut projecting from the anterior wall of the cervix, removed by Wertheim's operation, which, on pathological examination, showed an adenoma with no definite evidence of malignancy. He had taught for many years that cancer of the cervix could be diagnosed, practically always, by the finger or a Volkman's spoon. He considered it unnecessary, and often harmful, to cut away a piece for microscopic examination before operation, but showed this specimen as an instance in which a mistake in diagnosis would have been prevented by a microscopic examination.

Dr. Croft showed a specimen of fibrocystic tumour of the ovary. The major part of the tumour consisted of dense, fibrous tissue in which a few strands of involuntary muscle fibres appeared. Several cysts were present, one the size of a fist and the others from one half to two inches in diameter. The walls of two small cysts were calcified. This was no doubt a fibromyoma of the ovary, showing the unusual development of cysts.

Reviews.

ALLBUTT'S SUMMARY VIEW OF ARTERIO-SCLEROSIS

THE LATE SIR CLIFFORD ALLBUTT'S recently published *Arterio-sclerosis: A Summary View* has its saddening associations. Though to the last mentally as young and progressive as ever, he had been conscious of physical failure, and so was almost feverishly anxious to finish what he felt would be his last utterance. He did, indeed, succeed in completing a work which contains references to papers by others published as recently as January last, but he was never to see any of the proofs of this much expanded lecture to a post-graduate class in Cambridge. It was characteristic that, not content with his classical two volumes on *Diseases of the Livers, including Angina Pectoris* (1915), he continued to work, to collect fresh observations, and keep up with the literature on the subject of hypertension with which his name must long be intimately associated. This essay, divided for convenience into six chapters and provided with an excellent index, is written in the attractive style so characteristic of the scholar-physician whose modesty perhaps somewhat hid his real greatness, so that time will probably even heighten our appreciation of this master mind.

At the outset the reader's critical sense is whetted by the probing of the meanings of the abstract phrases so glibly on our lips, which appear to give more satisfaction than their unaltered interpretation really justifies. "Intestinal toxins" is criticized as a most pernicious catchword, for, as someone said of another writer, "we are guessing in the dark about a guess in the dark." Arguments are later brought forward against the popular view that arterio-sclerosis is due to poisons manufactured in the intestine, on the grounds, among others, that most of these bodies are depressor and asphyxiating rather than pressor, and the production of hypertension is referred to "a wisp of metabolism, possibly in the liver." But later he adds that if he were to suspect intestinal toxins as a cause he would give large doses of charcoal and might try kaolin.

The discussion of morbid anatomy carries the story pleasantly back to the far-off battle, some fifty years ago, when he had the opportunity of comparing the microscopic sections of George Johnson on the one hand, and of Gull and Sutton—or, as his friend Dr. W. H. Dickinson used to call them, "the allies"—on the other hand, the appearance of alleged hypertrophy of the muscular media he regards as one of increased tone only, under the influence of some cigot-like poison. After a generous reference to Dr. H. Batty Shan's monograph on *Hypertension and Hypertension*, the first of these two conditions is defined as a disease independent of the kidneys, with its own characters, of which high arterial pressures, systolic and diastolic, seem to be the chief, while hypertension is a general term for incidental high blood pressures. That some normal individuals have a systolic pressure of 160 to 170 mm. Hg he does not believe, though he cannot deny this statement any more than that in some "normal persons" the bowels act only once or twice a week. Insistence is laid on the instability of abnormal pressures, whether high or low, and on the probable occurrence in the subjects of intermittent phases of indisposition, recurrent headache, "suppressed gout," or "biliousness," of periods of high blood pressure as part of some obscure metabolic perversion or transient toxæmia, investigation of which, though they are perhaps difficult to catch, may throw light on the causes of hypertension.

In the chapter attractively entitled "Clinics" Sir Clifford Allbutt's long experience sounds the warning that, in spite of the general and more optimistic opinion, dyspnoea, however slight, means that the hypertensive patient whether renal or non-renal and even though blissfully unconscious of illness, has entered, not upon the first, but upon the last stage of his malady. He points out that uræmia occurs in cases of hypertension without any renal change, and is emphatic that severe uræmia even with neuro-retinitis may occur in cardiac disease in which the

kidneys show nothing more than congestion. But the outlook is widely different in the renal and the non-renal cases, for when the kidneys are capable of recovery the uræmia may be transient, and in the majority of such instances recovery follows a first or even a second attack. The slight and often transient paralyses or aphasia the "slight strokes" often by "sanguine pathologists" ascribed to passing spasm of the cerebral vessels, are regarded as of the worst urgency and probably due to small haemorrhages. Sir Clifford reiterates his opinion that in the majority of patients with angina pectoris the blood pressure is not raised, and says that in practice the cases with high pressure are more amenable than the ordinary run to treatment or to cure, but there is not any reference to the surgical treatment of angina, on which Professor K. F. Wackebach lectured at the Royal College of Physicians last year when Sir Clifford spoke so finely and impressively (vide *BRITISH MEDICAL JOURNAL*, 1924, 1, p. 828).

The chapter on treatment is valuable, especially for its wise and wide survey. In speaking of the insidious onset and the suggestion that everyone should be examined and have the blood pressure estimated every five years, the comment follows that "this rule would indeed set up an epidemic of fidgets." The doctrine not to treat high blood pressure as such on the ground that it is merely a symptom, and that it is "compensatory," and so would be an unscientific therapeutic procedure, meets with scant sympathy at his hands. The action of vasodilators is transient and gives but momentary relief, too strict a diet is inadvisable, and, like vasodilators, vasectomy is disappointing though useful at times. For iodides, which he usually gives in 1-grain doses twice or thrice daily in atherosclerosis with or without high pressure, no enthusiasm is expressed, but spirit treatment under watchful guidance is admitted to be very helpful though the fish air, change of scene, and attendant freedom from worry are far more important than "the water chemicals." The recent use of diathermy is recorded and the sphere of utility of endocrine preparations philosophically considered.

In conclusion, short as is the "Summary View" it is a welcome and useful record of the mature and wise final expression of the great Regius Professor's long experience, and will therefore appeal to the profession of which he was eminently the recognized leader.

HUMPHRY ROLLSTON

THE CELL IN DEVELOPMENT AND INHERITANCE

THE title of the first edition (1896) of the work by Professor Wilson of the chair of biology at Columbia University, U.S.A., was *The Cell in Development and Inheritance*, and as such for the next ten years we accounted that work one of the most valuable of the monographs of the Columbia University Biological Series. But much of the water of life has flowed under the morphological bridges within the last thirty years.

The first edition had 377 pages and 142 illustrations, as compared with the 1232 pages and 529 illustrations of the splendid work before us.

In the new edition the old title is slightly altered, but no title of reasonable length could describe the contents of this storehouse of facts and theories, for here are treated in the fullest manner possible all of the following. The general morphology of the cell, cell division, reproduction and cell life, gametes, fertilization and parthenogenesis, meiosis, sexuality in lower organisms, cell chemistry and cell physiology, chromosomes and sex, heredity and the chromosomes, growth and cell development, and development and heredity.

We are left in doubt which is the more worthy of admiration—the complexity, resource and infinite variety of Nature or the vast patience of the author of this treatise. We are particularly glad to find that this book so up to date in every respect, yet opens with a sympathetic recognition of the place of the cell theory of Schleiden and

The Cell in Development and Heredity By Edmund B. Wilson. Third edition. New York: The Macmillan Company, 1925. (Med. 8vo, pp. xxxvii + 1232, 529 figures, 36s. net.)

Schwann in biological history. For there has been of late a tendency in certain quarters to belittle the importance of that generalization made under the disadvantageous conditions surrounding the study of life nearly one hundred years ago. So wholly praiseworthy is Professor Wilson's view on this subject that we must quote his opening sentences:

"Among the milestones of modern scientific progress the cell theory of Schleiden and Schwann, enunciated in 1838-39, stands forth as one of the commanding landmarks of the nineteenth century. Its importance is not to be judged by its original form, as first outlined, it was but a rude sketch, in many respects faulty and distorted. Its announcement nevertheless marked a turning point in the advance of biology, opening a new point of view for the study of living organisms and revealing the outlines of a fundamental common plan of organization that underlies their endless external diversity. The cell theory thus became a perennial source of fruitful researches, which, down to our own day, have continued to press forward into always expanding fields of discovery. Long ago it became evident that the key to every biological problem must finally be sought in the cell, for every living organism is, at some time, has been, a cell."

Words as true as they are necessary.

It should not be supposed that this book is just a catalogue of facts of microscopic cell morphology, such as highly interesting and speculative topics as living matter, a continuum, the immortality of protoplasm, syngamy, senescence and rejuvenescence, rhythm, rhythm, and many other theories of fundamental interest are discussed. The bibliography alone is extremely valuable, and there is a welcome glossary of terms. There are two indexes—one of authors, the other of subjects. The figures throughout are exceedingly clear.

NERVOUS DISEASES

In the preparation of the second edition of his textbook of nervous diseases¹ Professor HANS CURSCHMANN has had the assistance, as co-editor, of Professor FRANZ KRAEHLER of Berlin, during the fifteen years which have elapsed since the first edition appeared three of the original contributors have died—Professors HANS STEINER, MAX ROTHMANN, and MAX LEWANDOWSKY. To the new volume there are twelve contributors, including the two editors, it contains over nine hundred pages and there are some three hundred illustrations, many of them photographs of cases, carefully chosen and exceptionally good, and constituting in themselves a very useful study. After an opening chapter by Professor KraeHLer on the general examination of cases of nervous disease, the book follows in anatomical basis, diseases of the peripheral nerves being first considered by the same writer. Professor F. K. WALTER deals with the diseases of the spinal cord and medulla oblongata, among which is included disseminated sclerosis, before the individual diseases are described full accounts are given of the anatomy and physiology and of the regional diagnosis of cord lesions. The myopathies, including dystrophia myotonica and myasthenia, are discussed by Professor CURSCHMANN. Professors HUGO LIEPMANN and KRAEHLER contribute a detailed chapter on the general anatomy and physiology of the cerebrum and cerebellum, the methods of examination and localizing features of brain lesions, and an account of the different types of aphasia. Chapters follow on meningitis and hydrocephalus by Professor HUGO STAECK, on brain tumour and brain abscess by Professors LEWANDOWSKY and GEORGE SEITZ, and on cerebral syphilis by Professor R. GRUPP. Professor SEITZ deals with encephalitis and vascular lesions, with diseases of the extrapyramidal system, and with certain types of idiosyncrasy, all the accounts are thoroughly up to date and are well illustrated. An interesting section on the physiology and pathology of the vegetative nervous system, written by Dr R. GIEVING, is followed by a chapter by Dr CURSCHMANN on nervous disorders associated with the endocrine organs (exophthalmic goitre, myxoedema, tetany, acromegaly and Frolich's syndrome, and lipodystrophy). Vasomotor and trophic disorders are considered by Professor CURSCHMANN, and nervous diseases due to intoxications by Professor F. QUENSEL. Lastly, there are accounts of the orthopaedic treatment of nerve lesions by Professor H. v. BAAYER, and

of the surgery of nervous diseases by Professor FEDOR KIANSE.

This book is a comprehensive manual of nervous diseases. It contains sufficiently detailed accounts of rare diseases to be of value both to neurologists and general physicians, and it should prove an excellent book of reference for the practitioner who desires to keep in touch with modern neurology. A textbook of this standard in English, but not a mere translation, seems to be needed.

NOTES ON BOOKS

THE editor of the history at home and abroad of *The 21st London Field Ambulance* during the great war is to be congratulated on having produced a most readable book, which can be read with interest by those who had not the good fortune to serve with the unit whose exploits it commemorates. After preliminary training in England the unit left Ipswich at midnight on 1 February 20th-21st, 1916, touched at Southampton, left there for Le Havre on the evening of 1 February 21st, and thence proceeded to the village of Atraines, there it joined the 56th Division, with which it served for the remainder of the war. It received its first real glimpse of heavy fighting in the Somme area, and, after doing duty at the capture of Combles, was moved to the La Bassée-Laentie area, where fighting was of a less exciting nature. Here it stayed until March, 1917, when it moved towards Arras for the first Arras battle. Next it visited St. Omer and shared in the third battle of Ypres, after which it went to Bapume and wintered at Aubigny. In March, 1918, the unit went through the famous German offensive against Cambrai and from that time to the close of hostilities took part round Arras in the many engagements which preceded the German retirement, finishing up at Query le Petit on the eve of the signing of the armistice. After further moves later to Mons and Jemappes the unit was sent home by way of Antwerp and demobilized at the Crystal Palace. Its roll of honour comprised twenty-four names, and its honours and awards numbered forty-two, including four mentions in dispatches. The book is well printed and illustrated with photographs and sketches. A foreword by Lieut. Colonel C. S. BRENNER, D.S.O., who commanded the unit from its foundation until after the armistice, explains the reason for the delay in its appearance. Copies may be obtained from H. L. Chase, "Kingsley," Merstham, Surrey.

Rice is, it has been stated, the staple food of more than half the population of the world. If for that or for any other reason a reader of the *BRITISH MEDICAL JOURNAL* should take it into his head to cultivate rice he will learn to what countries he may go and all about its production from a little book² by Mr C. E. DOUGLAS. It appears to be the first work published on the subject, and deals with it in every aspect—historical, ceremonial, botanical, physical, with the details of its cultivation, with its relation to soil, to climate, to its food value, and, finally, with exactly the right way to cook rice and prepare a rice pudding—which is undoubtedly useful knowledge if duly applied. The little book is one of a long and excellent series issued by the same publishers on common commodities and industries.

PREPARATIONS AND APPLIANCES

A Self-retaining Anal Speculum

MR. HAROLD BURROWS, O.B.E., F.R.C.S. (Southsea) informs us that Messrs. Arnold and Sons (John Bell and Croyden, Ltd.) 50-52, Wigmors Street, W.1, have recently made for him a small self-retaining speculum, which is especially useful for the injection treatment of piles. On the end of the speculum is a bulb which renders it self-retaining, so that the operator has both his hands free.

Using Testing by Diabetic Patients

DR. A. CLARKE BEGG (Swansea), having found the advantage of diabetic patients examining their own urine regularly, has devised, and Messrs. Allen and Hanbury, Ltd. 48 Wigmors Street W.1 have made a small outfit for their use. It is packed in a wooden case which contains Fehling's solution No. 1 and 2, the (dilute) solution of non-perchloride spirit lamp, half a dozen test tubes, a notebook to record daily results, and full directions for the test. Dr. Begg recommends Fehling's instead of Benedict's test as all medical men are familiar with the former and can better assist the patient if he gets into difficulties. Dr. Begg thinks it essential that patients should test occasionally for diuretic acid, and should be instructed to get medical advice at once if any red coloration is shown with the iron perchloride.

¹*Lehrbuch der Nervenkrankheiten*. Herausgegeben von Dr. Hans Curschmann, Ro. tock und Dr. Franz KraeHLer. Berlin. Zweite Auflage. Berlin Julius Springer. 1925. (Roy. 8vo, pp. x + 952. illustrated. G.M. 36.)

FIRST INTERNATIONAL CONGRESS OF RADIOLOGY.

LONDON MEETING

THE International Congress of Radiology, the opening of which was reported in our last issue (p. 32), closed on July 4th, after a very successful four days' meeting at the Central Hall, Westminster, under the general presidency of Mr C THURSTON HOLLAND, C.B.M. The British organizers had described it as a "preliminary meeting," but directly the Congress assembled a meeting of the international delegates resolved to declare it the First International Congress of Radiology, and to elect Mr Thurston Holland as its President. At a later meeting of the delegates it was resolved that the Congress should meet next in Stockholm in 1928 under the presidency of Professor GOSTA FORSSSELL. Some general principles were adopted for the guidance of future Congresses, one of which was that any country having a radiological society or societies should be entitled to send not more than five official delegates, but that only one vote should be exercisable by each country. Professor Forssell was appointed chairman, Mr Thurston Holland vice-chairman, and Dr Stanley McWhille secretary, of the international delegates' committee, pending the next meeting of delegates.

The proceedings of the Congress took place in three sections. The Section of Physics was presided over by Mr C. L. S. PHILLIPS, the Section of Electrophysics and Actinotherapy by Sir HENRY GAYLOR, and the Section of Radiology was divided into two parts—one for the discussion of radio-diagnoses and the other for the discussion of treatment by radium and x-rays. Dr A. E. BARCLAY presided over the first, and Dr N. S. FRYER over the second. These two halves of a section each carried out a very full and well co-ordinated programme, the one beginning with radiological diagnosis of bone conditions, and passing on to the gall bladder, the alimentary tract, the thorax, and the skull, while the other devoted three sessions to radium therapy and three to x-ray therapy. The number of papers read was 150. It is possible only to note some of the outstanding communications.

RADIOLOGICAL DIAGNOSIS

The Position and Form of the Stomach

Dr R. O. MOORE (Oakland, California) brought forward the results of an x-ray study of the living anatomy of the stomach, liver, and colon in 1,000 healthy adults. He showed that in 75 per cent of the male subjects the lowest part of the greater curvature was below the interiliac line, and that this position was most frequently in a zone from 2½ to 5 cm below that line. In the female subjects the lowest part was below the line in 88 per cent of the cases examined, and in 43 per cent was more than 5 cm below the line. In 12 per cent of the males and in 30 per cent of the females the lesser curvature also was below the interiliac line. The pylorus in both sexes was most often found well below the transpyloric plane. All these were thoroughly normal and healthy subjects. He held that the use of the term "gastroptosis," like "coloptosis" also, was seldom justifiable—the form, position, and relations of the abdominal viscera differed so widely among normal individuals.

Dr I. S. HINSCHE (New York) complained that his compatriot had made no mention of the great work on this subject done by Mills of St. Louis, who had shown, after many years of very careful examination, that there was a definite relationship between visceral form and bodily habitus. Dr Moore said that he fully appreciated Mills's work, though he did not think that the position of the stomach could be so exactly guided according to changes in the bodily habitus as Mills had described. With regard to the need of this work, it was enough to point out that both in England and America there were thousands of physicians who regarded a "fallen" stomach or "fallen"

colon as symptomatic of ill health, when actually this was not the case.

Professor GOSTA FORSSSELL (Stockholm) urged the abandonment of the terms "hypertrophic" and "hypotrophic" as applied to the stomach, because these terms indicated an abnormal state, whereas both types were quite normal. One of these states was adapted to certain physiological conditions, and the other to certain different conditions, but equally physiological. Often in textbooks there was mentioned a hypertrophy of the pylorus in children, but as a rule there was no such hypertrophy. The condition did not really relate to the pylorus at all. It was really a case of contraction—perhaps sometimes a real hypertrophy—of the pyloric canal, not of the pylorus.

In discussing a paper by Dr DE BACKER (Ghent), giving the results of a radiological study of the digestive tract in normal children, Dr LE WILD (New York) said that the colon in children needed a great deal more elucidation. The statement that the long colon in the child would necessarily be outgrown was an error, this type of colon might persist throughout life.

The Art of Palpation

Dr A. E. BARCLAY (Manchester) said that palpation under the x-ray screen was a complex art, and one which was not acquired without much patient practice. It was not an art learned at the bedside, what it required was not only a delicate sense of touch, but a complex of touch and sight. It was of the greatest possible value in detecting the final changes in the stomach and other organs. The most important palpation of the stomach was that which was done while the first mouthfuls of food were passing down. Here a little pressure would often bring out a filling defect, more especially as to the margins. No matter with what care palpation was done, however, plates also were necessary. Radiologists should always attempt to show on their plates what they detected by palpation, and the success of a screen examination must not leave the radiologist content with faulty radiographic records.

Diverticula of the Small Intestine

Dr J. T. CASE (Battle Creek, Michigan) gave an interesting account, illustrated by radiographs, of some 70 cases of diverticula he had observed. One point was that in cases of multiple diverticula it was always found that the larger diverticula were nearest the stomach, and the smaller ones further away. By x-ray findings he had been able to differentiate between true and false diverticula. Of his 70 cases a number were found only at autopsy, some were found at operation for acute trouble apparently not related to the diverticulum. About three-fourths of the patients had no symptoms due to the diverticula, they died or they came to operation from some other cause, only in one-fourth did the need for operation arise or a fatal issue occur owing to pathological changes in the diverticula. In other words, the diverticula were subject to the same changes as the appendix.

The Mucous Membrane of the Digestive Tract

Professor FORSSSELL (Stockholm) offered some observations on the motor mechanism of the mucous membrane of the digestive tract, and showed some pictures demonstrating unmistakable variations in the relief of the mucous membrane in one and the same loop of the small intestine. He said that typical dissimilarities in the x-ray picture were not caused by different fillings, but by a real dissimilarity in the folds. He had tried to obtain more knowledge of the nature of the movements of the intestinal mucous membrane by means of direct observation, and he had found what he held to be convincing proof of the active participation of the mucous membrane in the movements which brought about a change in its relief. It seemed probable that the musculature would exhibit the

phenomenon of contraction at the place of the fold, he had made histological preparations of different parts of the alimentary tracts of men and of animals, and these had proved that the overlapping muscular cells in the muscularis mucosae occurred typically in the folds of the mucous membrane, being most marked at the tips of the folds, so that the muscularis mucosae within the area of the folds often attained a thickness several times greater than in the furrows between the folds. This phenomenon of overlapping was most marked in the stomach cavity, but it was quite distinct in the small intestine also.

Dr H. M. INNOMIS (New York) spoke on the observation of intermittent obstruction of the small intestines. This work, he said, depended upon screen examination, he was unable to make a diagnosis from the plate. The screen examination, moreover, had to be very painstaking, if it was to elicit the required information. The writhing and twisting of the duodenum and its marked inability to empty itself were perhaps the most characteristic signs.

Radiology in Thoracic Surgery

Mr. MORRISTON DAVIES (Ruthin) said that in thoracic surgery, where accurate diagnosis and localization were necessary as a preliminary to treatment, the clinical methods of examination were incomplete and not sufficiently discriminating. Radiology was not a substitute for clinical examination, but both in diagnosis and during the course of treatment it was such a valuable adjunct that treatment should not be carried on without resort to this method for checking the clinical findings. He referred to certain cases in which the diagnosis was possible only by x-rays. One patient was sent to him for bronchitis and emphysema, and clinically there was nothing suggestive of anything beyond those conditions, but on x-ray examination it was possible to diagnose primary broncho-ecarcinoma, for which the patient was operated on later. Another case was that of a girl with curies of the spine and with a little patch of dullness at the back of the right lung. By x-ray examination, and by that alone it was possible to make a diagnosis of hydrath of the lung. A woman who had been treated for thirty years at a general hospital for dyspnoea and palpitation, and was sent to him as a case of basal pneumothorax, proved on x-ray examination to have a diaphragmatic hernia. Another case was sent to him as early tuberculosis, and the x-rays showed a gumma in the upper lung. Another patient who presented only laryngeal symptoms was proved by x-rays to have military tuberculosis. The rays would frequently show greater changes than the hand or the ear could detect. Radiology was of equal importance during and after operative measures.

Detection of Non-opaque Foreign Bodies

A paper which called forth the special reclamations of the Section was read by Dr W. F. MANGES (Philadelphia) on the detection of non-opaque foreign bodies—usually nutshells and other hard vegetable substances—occasionally bones—in the air passages and food passages. Dr Manges's method was to watch the respiratory movements during inspiration and expiration, taking the x-ray picture at the full extent of both these acts, and by a comparison of the air entry to the lungs and the displacement of the mediastinum and heart he was able to arrive at the exact situation of the non-opaque body. The patients—usually children—were placed with the arms above the head, the face directly forward, the tube 36 inches distant and centred very carefully in the middle line, and the exposures were made as short as possible, the same exposure being given for expiration as for inspiration otherwise the impression of density on the two sides was unequal. The knack of making exposures at inspiration required to be developed—one had to learn to "shoot on the wing." The difficulty at expiration was not so great, because here there was a certain prolongation of the moment of rest.

X-ray Examination of the Male Urethra

Dr E. H. P. CAYE (Hullow) read a paper on the x-ray examination of the male urethra. The methuoscope although it must have first place as an aid to diagnosis

had certain limitations. With radiography it was possible to penetrate further and to visualize the whole course of the urethra. Cases of prostatic enlargement formed a group to which this method was applicable. The degree of enlargement of one or both lobes was clearly visible in the radiogram, and by repeated examinations the rate of growth could be determined. Similarly, in post-prostatic cases the contraction of the prostatic cavity could be observed by the same means. Radiography, again, could throw new light on the sphincteric action in normal and pathological conditions. He described the technique to be employed in using lipiodol, and the proper way of taking radiograms of the part. The injection was painless and discomfort to the patient was considerably less than that caused by urethroscopy or cystoscopy, and no ill effects, immediate or remote, were experienced.

The Venous System

Dr M. C. COSMAN (Boston) reported on a comprehensive study of brain tumours by means of x-rays. Certain of these tumours gave signs that furnished a clue, not only to their location, but to their type. In gliomas only 11 per cent might be expected to be seen radiologically, but pituitary tumours were characteristic, and meningiomas showed recognizable changes. In ten cases which came under his observation aneurysm of the intracranial portion of the internal carotid diagnosed radiologically had been confirmed either by operation or autopsy.

Among several other papers dealing with the localization of brain tumours and compressions of the spinal cord was one by Dr Jacques LOURISTIN (Aix les-Bains), in which he described the value of radiologic diagnosis by the lipiodol method for localized compression in the spinal cord as well as for exploration of the bronchial tree. He said that lipiodol was eliminated after a time, and did not act as an irritant.

The papers on radiological diagnosis were so numerous that there was little time for discussion. Moreover, very many of the papers—and those some of the most valuable—were scarcely intelligently reported without the illustrations which accompanied them. Very frequently the illustrations overshadowed the text. This applies to such papers as that by Dr H. J. P. PIER (Montreal) on normal varieties of bone simulating disease, to the very able paper by Dr WOODWARD MORISON (Manchester) on diaphragmatic hernia to Professor KILIAN's anatomical atlas of the x-ray signs in phthisis, and to the whole group of papers, chiefly by American and German authors, on cholelithography.

Cinematograph Demonstration

Two or three of the papers were illustrated by the cinematograph. Dr FRANKEL (Berlin) gave by this method a demonstration of a new symptom of ulcer ventriculi within folds. Dr L. G. COLE (New York) showed a long reel of cinematograph film, which had been produced under his direction, to illustrate the anatomy, physiology, pathology, and radiology of the stomach. The gastric cycle and the action of peristalsis were wonderfully well shown. All the ingenious devices of screen production, familiar to the public in the animated cartoon of which the immortal "Felix" is an example were employed to tell either the profession or the public—one was not sure which—everything that could be told about the stomach, and the film ended with some comic "business," in which a surgeon and a physician, supporters of rival theories, were left belabouring one another in true knockabout style! Dr Cole also showed a very elaborate film production illustrating tuberculosis, once again with all the brightness of subtitles and "close-ups," and the movement of inanimate objects—a curious and clever mixture of scientific demonstration and amusing entertainment.

RADIOTHERAPY

Radiation in Cancer of the Breast

Dr CASMAN (Antwerp) showed a remarkable cinematograph film illustrating the operation, in an actual case, of burning radium tubes in the breast. In cancer of the breast he favoured a combined method whereby x-rays,

radium, and surgery were all employed. Each of these agents used alone had its limitations. The difficulty with surgery was twofold: the unsuspected extent of the lesion and the anatomical impossibility of the extirpation of the tumour. The percentage of surgical successes left very much to be desired. The difficulty with x rays was to ensure that a sufficient amount of x -ray energy was absorbed in the tumour. Radium had a more limited field than x rays, but its action was more powerful. He began his treatment of a case with the x rays, making them embrace the whole area of infection as far as possible, thus, as he described it, "rounding up" the cancer. Some four or five weeks after the x -ray application he made a small "corner-shaped" incision and carefully buried radium tubes surrounded by gauze and fixed at a certain distance from the edges of the area to be treated. By using this method he had been able to employ an intensive radiation without menaces to the adjoining tissues, the radium being buried at some distance from the skin. In estimating the radium dosage the x -ray irradiation which the tissues had absorbed must not be lost sight of. Dr. Casman contented himself with the film demonstration of his technique and did not enter upon a discussion of comparative results.

Dr. BURTON J. LEE (New York) gave a report on a series of eight primary operable cases of carcinoma of the breast from the Breast Clinic of the Memorial Hospital in his city. All these cases had been treated entirely by irradiation, without surgery at all. A period of four and a half years or longer had elapsed in each of the cases since treatment was begun. The reason for withholding surgery was either the age of the patient or her refusal to submit to operation. He had to confess, however, to a considerable pessimism with regard to the end results of surgery in the treatment of mammary carcinoma. In this group of eight cases the oldest patient was 90 years of age, by the introduction of radium tubes she was made comfortable for three years until her death from intercurrent disease. The average age of the patients was 58, the rate of growth of the disease in six of the patients was slow, and in two moderate. Axillary nodes were palpable in two of the patients. In the three cases in which biopsy was done the result showed carcinoma simplex. Three of the patients were treated entirely by x rays, of these one was alive, and the other two had died respectively two years and four years following treatment. Radium was used alone in two patients, and radium and x rays combined in the other three. The radium used was approximately 1 millicurie per cubic centimetre, and the x rays were from a low-voltage tube, 6 min. exposure, focal skin distance 10 in., filtration 3-4 mm. aluminium. Of the eight cases five were now alive and well, two had died from intercurrent disease, and one of metastases. He held that radiotherapy was the treatment of choice in primary operable carcinoma of the breast in those of advanced age, and was justifiable if surgical intervention was refused, the results in this limited group of cases might be compared with the results obtained in surgery without disadvantage to radiotherapy.

Inoperable Carcinoma of the Cervix Treated by Radium

Dr. MALCOLM DONALDSON reported on 85 cases of inoperable carcinoma of the cervix treated by radium. His paper embodied the conclusions given in his article in the *BRITISH MEDICAL JOURNAL*, May 9th (p. 876). He added that he was still in doubt as to whether it would be better further to increase radium intensity (either per unit of needle or by inserting more needles) or to increase the duration of application. Although the cases treated by his latest technique were an improvement on the previous ones, yet in those cases which were not doing well the site where growth went ahead was more often in or around the portion of the rectum lying beneath the vagina. It had occurred to him that this was due to the fact that the intensity in that area had been too much diminished in the effort to get the bulk of the radium against the more localized growth in the broad ligaments. In his next series of cases he intended that the time factor should be the same—namely, 144 hours—but that the number of needles should be increased, several being placed around

the lower part of the rectum. He realized that by so doing a great deal of proctitis and even fistulae might be set up, but possibly the fear of this complication had been the cause of this portion of the body being left at the mercy of the cancer cells.

The paper was discussed by Professor DAELS (Ghent), Dr. BURTON LEE (New York), Dr. M. R. J. HARRIS (Dublin), and others. Dr. ZWEIFEL (Munich) said that at his clinic radium had been used in cancer of the cervix, but subsequently a combined method of radium and x rays was chosen. Among the operable cases there had been 43 per cent. of cures, and among inoperable ones 7 per cent. of definite cures. He hesitated to include the more recent cases, but he believed the proportion of cures would prove to be higher, thanks to the combined method now used. Professor HERMANN WINTZ (Erlangen) said that squamous carcinoma of the cervix was much more sensitive to x rays than to radium.

The Encirclement Method of Radium Treatment

Mr. SIMPSON HANDLEY (London) described his encirclement method of radium treatment. He said that every aggregation of cancer cells had a definite life cycle, and after increasing in size for a varying period and at a varying rate tended spontaneously to undergo fibrotic changes. The centre of a mass already degenerating or dying would succumb to a much smaller radiation dose than the actively growing periphery. Attention might almost be concentrated on the periphery and the central portion left to take care of itself. The disappearance of a lump of malignant tissue was not of so much importance as the arrest of its spread. In addition to the spread of a nodule by infiltration, cancer cells spread by permeation of the lymphatics, a process which, when once it started, would outstrip the process of infiltration. Often it was best to ignore altogether for the time being the visible deposit and to direct attention entirely to the zone of infiltration and of permeation surrounding it. The radium tubes should be so arranged as to give a lethal dose to that zone. Afterwards, if the nodule had not disappeared, a second irradiation might be given in a narrower circle, and later still, if a vestige remained, another irradiation on the nodule itself.

Malignant Disease of the Upper Air Passages

Mr. DOUGLAS HARRIER (London) said that sarcomas of the upper air passages, especially those of the round-celled type, invariably reacted well to radium treatment. He spoke of cases which had been treated in this way five years ago, and were now completely well and apparently cured. In endothelioma there were some equally remarkable results. In this condition radium might be taken as having diagnostic value. If a tumour was a true endothelioma it would almost entirely disappear under radium. Radium was not equally successful in all diseases of the upper air passages, but in carcinoma of the larynx and some other conditions he thought that surgery by itself had seen its day.

Dr. C. REGAUD (Paris Radium Institute) spoke of the treatment of epithelial cancers of the tongue and floor of the mouth. Out of 174 traceable cases in which treatment had taken place from one to five years earlier, 42 were alive and without any symptoms of cancer—50 per cent. of these had been operable cases and 34 per cent. on the border-line—and another 39 showed healing of the localization in the tongue and apparent sterilization, but had died or were expected to die of adenopathy. The principle of treatment had been to distribute numerous weak radio-active foci in and immediately around the cancerous part, to use the gamma rays only, and to give continuous irradiation over a long time.

Radium Therapy in Various Conditions

Dr. S. A. HEYERDAHL (Oslo) spoke on actinomycosis treated by radium. His first case, before coming for radium treatment, had been operated on twice without permanent result. Radium treatment was tried in 1913, and after ten years there was no relapse. Later he had had the opportunity of treating 17 men and 4 women with

radium, giving usually two or three applications with intervals of six weeks. In all cases there were good results, which had continued up to the present, the treatment dating back for from two to ten years.

Dr F. TOMISIK (Pisguc) gave an account of the treatment of pernicious anemia by radium. He had tried to diminish the activity of the spleen by massive irradiation over long periods, and he had succeeded in twenty cases in which other methods, including blood transfusion, had not succeeded at all. He recommended radium treatment in preference to splenectomy. He also gave an account of the effects of prolonged irradiation in Pisguc during the last few years he had employed a method of protected radium irradiation of the spleen, using 2 mm zinc filters, at a distance of 3 cm. He used 80 to 100 mg of radium, dividing up the tumour area into twenty five small fields and treating each field successively for one or two days. The blood picture greatly improved. Dr R. H. STIVERS (Detroit) said that during the past year he had treated four cases of leukaemia with intravenous injections of radium in order to get the prolonged action of comparatively small doses. Three cases had not been very successful—two, in fact, had died. But in the fourth case the injection of 200 mg was given last October, with marked improvement in November, and the patient had another 200 mg in January. Before the first treatment his blood count was something like 200,000 leucocytes, but since the second injection it had been normal. This patient had previously been irradiated for five or six months, but did not seem to respond, and that was the reason why intravenous injections of radium were given.

Altogether about thirty papers were contributed on the subject of radium, some of them recounting a single observation and others founded on a vast experience. Among the latter was the paper by Professor A. BAYER describing the practice at the Brussels Radium Institute in treating various cancers by a combination of surgery and radium and sometimes a ray also. The total number of cases so treated during two recent years was 742. The results had been particularly satisfactory in cancer of the rectum and cancer of the uterus. He insisted that no one method must be considered as subordinate to any other. He did not approve of the subordination of radium therapy to surgery, as practised in France and in other countries.

X-Ray Treatment of Breast Cancer

Professor HERMANN WITZ, of the Erlangen Clinic, described the results in 106 cases of breast cancer treated by x rays which had been observed for a period of three years following treatment. He divided the cases into three groups: (1) those in which the tumour was restricted to the breast and could be moved, and in which there was no infection of axillary or supraclavicular glands, (2) those in which the tumour had already infiltrated the surrounding region, and axillary glands were palpable, (3) those in which the glands in the supraclavicular region were palpable, and in some cases metastases were also apparent. The cases were those in which on careful examination no trace of cancer could be found, "lost" cases those in which the patient had died or was in a dying condition, and those who could not be followed up.

Group (1)	Treated	Cured	Lost	Clinical Cure
Group (2)	21	20	1	95.2%
Group (3)	41	28	13	68.2%
	44	8	36	18.1%

He noted that in groups (2) and (3) the results were better than in surgical statistics. It was essential that the requisite dose for the destruction of the carcinoma cells should be applied to the axillary and supraclavicular regions as well as to the tumour itself, and of equal importance was a carefully planned scheme of after-treatment. Care must be taken to avoid lung fibrosis, and by adjustment had been brought down to 5 per cent. He found the percentage of successes in primary x-ray treatment considerably greater than in prophylactic x-ray treatment after operation, and he had abandoned prophylactic x-ray treatment in the strict sense of the word, preferring to wait until the nodules on the skin or the gland metastases gave pronounced indications for treatment.

Dr DOUGLAS WINSTON brought forward the results of x-ray treatment in 15 cases of operable carcinoma of the breast. At the present stage irradiation should not be advised in preference to operation or operation was made when patients refused to discuss the technique and results of irradiation treatment. Eight of his cases had been treated solely by x rays, two with radium insertion and x rays and five with surface applications of 0.5 gram radium element and additional x-ray applications. The interim results of the cases were too recent for detailed conclusions—suggested that radiation was a suitable alternative to operation in some operable cases, and the other of the disease itself intrinsically, and the other had been discontinued after two years after treatment had abdominal metastases after a patient. One patient had never cases, but one died acting well locally. Three were new cases, but one died showed no signs of the disease. In the remaining nine cases the general and local condition had taken place or the subject, remarked that statistics in breast cases, but checked on the average duration of untreated cases, it was true that surgical statistics came out very badly by this criterion, but Professor Wintz's figures, on the three year basis would always appear much too good, although, on the other hand, statistics after five, six, or seven years would tell unfairly the other way, because the methods of application had greatly improved since those early days.

The Stimulating X-Ray Dose

Dr E. H. ZWERNER (Munich) opened a discussion on "The stimulating dose." He described a number of experiments by various workers which went to prove the existence of such a dose. It had been shown that plant exposed to small doses of x rays grew more quickly than normal controls. Russ and others had found by experiment on mice a positive stimulation effect. In the irradiation of the tissues in fibroid an increased loss of blood had been noticed, especially when the treatment was given shortly before the period of calving after x-ray exposure. Nearly all malignant tumours could be influenced to more or less increase of growth. In a large number of cases of cancer of the uterus treated at the clinic at Munich many cases of commencing cancer, which if untreated would have lived at least a year, died within a shorter time—even as short as six months—after radium and x-ray treatment, and such cases suggested that it was the radiological interference which had led to the quickened growth. The dose applied in the depth had not been sufficient to kill the growth, but, on the contrary, had stimulated it.

Dr I. S. HENSEN (New York) thought that it was necessary to distinguish between the effect on the cell as an individual unit, on the tissue as a cell complex, and on the organ as a tissue complex. There was no question but that the effect on the individual cell was always in the nature of a "stimulus," an "insult," but in the complex structure of the tissue there came into play compensatory powers which might result in stimulation rather than destruction. Dr DOUGLAS WENSTON (London) said that it was clear from the examination of buds and plants under the microscope that there was a stimulation dose. There were also certain clinical cases which appeared to point to a stimulation dose, and it was dangerous to assume that there was no such dose without absolute proof of its non-existence. Professor WITZ (Erlangen) said that it was only a certain dose, measured by biological standards, which was stimulating. It appeared that 40 per cent of the unit skin dose might be considered a stimulating dose for a squamous-celled carcinoma. Professor BECKER (Paris) said that recent French research had shown that there was a stimulating action, but that it was feeble and of short duration. The effects might partly be due to secondary infection of a microbe character.

Methods in X-Ray Therapy

Dr G. E. FRAHLER (Philadelphia) described what he called the saturation method in x-ray therapy. The principle of it was to repeat x-ray doses at short intervals in order to maintain the erythema dose—which in the case

of unfiltered rays fell by 50 per cent in value in about three days—it approximately its original level. Thus, malignant cells while still undergoing division, received the prolonged maximum action of the rays. This method, which had advantages over the single massive dose, required careful measurement of the quality of radiation and accurate direction of "cross fire."

Dr ISAC GERBER (Providence) spoke of the usefulness of minute doses of filtered radiations in superficial pyogenic infections, particularly of the skin. Needle infections of surgeons had been completely aborted or promptly circumscribed by x-ray treatment. Deep phlegmons and cellulitis would localize very quickly, erysipelas also yielded to this treatment. The dose given was never more than 25 per cent of the skin erythema dose, and was as low as 6 per cent in children. This dose was simply applied to the surface, and in a great many cases a single exposure sufficed. Dr W. MICHURILL (Bradford) referred to the need for adequate filtration when attempting to deal with the conditions. Dr SCHNARUS (Düsseldorf) had proved that the excellent effects of x-rays in furunculosis were caused by an immunity to the staphylococcus developing after irradiation.

Effect of X Rays on Mitosis in Tissue Culture
Dr T. S. P. STRANGEWAYS and others who have been working with him gave a demonstration of their researches on the effect of irradiation on living tissue cells *in vitro*. The ultimate object of their work has been to find the optimum dose of radium or x-rays to destroy a cancer. They also exhibited stained specimens which showed the effects of exposing the cells to radium or x-rays. These brought out the effects of the radiations on actively dividing cells at certain distances and for certain times. A further demonstration given by these workers was of the internal structure and movements of the actual living cell, shown by means of dark-ground illumination.

ACTINOTHERAPY

Sir HENRI GAUVAIN opened a discussion on actinotherapy. He said that the treatment by light was based on clinical experience and observation. Use should by all means be made of the results of discoveries with regard to the action of light on the body, but these discoveries, sometimes apparently contradictory, must not be allowed to deflect the clinical judgement. The clinical result of the treatment given was the final thing to be considered. He himself was in the habit of describing the action of light as twofold—first, on the mind, and, secondly, on the body. At Alton it had been possible to demonstrate that, with exposure to light, there was a definitely increased response of mental health. With regard to the effect of light on the body, he thought it might be described as twofold. There was first the direct or local action, the effect of light on the skin, which was of various kinds, including inflammatory response and the formation of pigment. Some workers went so far as to urge that pigmentation should be avoided, but he believed that pigmentation should be important therapeutic significance. Patients who had a very marked well so frequently did well in other respects that there must be some association between pigment formation and therapeutic effect. Then there were the remote or indirect effects of light, with regard to which he did not propose to speak. There had been a tendency, especially in this country lately, to use very short-wave ultra-violet rays. These had a rapid and remarkable action, but very little penetrative power. He reminded the Section of the antagonism of rays—some rays appeared to stultify the effect of other rays. In fact, light therapy was in some ways the most intriguing of the therapies because of the unexpectedness (even if occasionally the confusing character) of some of its results.

Dr LEONARD HILL (London) gave what amounted to a lecture in this Section on sunlight and artificial sunlight treatment. He mentioned, among other matters, how entirely the effect of ultra-violet rays was screened off by garments, even by the thinnest zephyr. Artificial silk was the most permeable material, being an acetocellulose, whereas natural silk was a protein. If the patient receiving ultra-violet treatment insisted on being clothed the garment

should be an artificial silk zephyr. He went on to point out how little danger from sunburn existed in the smoke-polluted air of English cities, and gave some figures illustrating the striking differences between various localities, even between places so near together as Hampstead and Kingsway, at this last station the ultra-violet rays were not then minimum. There was no need in England to take all those precautions against sunburn which Rolher had found necessary at Leyden. Dr Leonard Hill described the action of ultra-violet radiation on the tissues, saying that it put up a general resistance, not a specific immunity, to infection.

Professor SEVER (Copenhagen) spoke of the action of ultra-violet and visible rays in therapy, and especially how visible rays, penetrating into the skin, heated up the subcutaneous blood. He also insisted on the advantage of radiant visible heat, such as the open fire or the gas fire. Dr R. G. BANNERMAN (Alton) dealt with some of the biological effects of mercury vapour lamps. It would appear that a massive dose of mercury vapour radiation was followed by a phase of depression of the organism, and therefore, while an erythematous reaction might be desirable or even essential in the local treatment of a local condition, it was to be avoided in the treatment of a general condition.

Dr S. ROTUNDO brought forward the results of some experimental research carried out at Giessen University dermatological clinic. The work had shown that in the case of light baths intensive reaction of the skin must be avoided on account of the danger of focal reaction. By combining light treatment with systematic hydrotherapy, massage, and exercises in the sun or in the artificial light bath, the best results were secured. Natural sun baths were best, with quartz lamps it was more difficult to make the pigmented skin hyperemic. It might be that the visible spectrum had a helpful effect, but without ultra-violet radiation no therapeutic effect was possible, whereas the visible rays could be dispensed with.

Dr A. EMMERSON (London) spoke on the bactericidal effects of ultra-violet rays, these effects could be seen when a very thin film of blood containing bacteria was exposed to an ultra-violet source. When photosensitizers such as eosin were added to the mixture of blood and bacteria the direct bactericidal action could take place upon exposure to visible light. Direct exposure of defibrinated blood to ultra-violet rays destroyed the bactericidal properties of the irradiated and slightly haemolysed after one hour's irradiation, and examined by the spectroscope, the presence of methaemoglobin could be detected.

Dr MORRIS LEVICK referred to the importance of red light as a physiological and curative agent. The red rays were absorbed by muscle and, he believed, by inflammatory exudate. Carbon filaments yielded a light much richer in red and infra-red frequencies than the ordinary metal filament, and the infra-red rays could be cut out by red-stained soda glass screens. To avoid undue heating the lamps should be placed at a distance of two feet, allowing of free circulation in the air around the part. He cited the value of red radiations in cases of musculo-wasting, tuberculous ulcerations, and other conditions.

Electrotherapy

One of the three discussions in this Section was devoted to electrotherapy, and was opened by Dr E. P. CUMMERBATCH, who referred particularly to diathermy, and continued by Dr WILLIAM BIERMAN (New York), who described his method of surgical diathermy in the treatment of haemorrhoids, which, he said, was a marked improvement on the cauterization that it caused less injury to the tissues and introduced heat in the most effective way. Dr S. JELLINEK (Vienna) gave an account, illustrated by some remarkable microscopic slides, of the bone changes, immediate and delayed, occurring after electrical shock.

International Units and Standards
The opening of the combined discussion by the Sections of Physics and Radiology on international units and standards for x-ray work was reported last week. A great

[2 JULY 11, 1925]

INTERNATIONAL CONGRESS OF RADIOLOGY

[The President
of the Congress]

part of the discussion dealt with the technique of physical measurement in a way which does not lend itself to a useful abbreviation. The feeling evident throughout the discussion was in favour of setting up a standard which should be expressed in terms of absolute units. Perhaps the most helpful thing was said by one of the British physicists, who declared that the necessary preliminary to a really universal system of measurement would be to arrive at a constant source of current for the tube. If a standard type of x-ray beam with a constant voltage apparatus were available, that beam could be measured in terms of the international unit, whatever that unit might be. The outcome of the discussion was a resolution to appoint an international committee to study the question of measurement. This committee was not appointed at the Congress, because it will be necessary to communicate with the various scientific bodies throughout the world in order to arrive at a representative membership, but it was agreed that the following gentlemen, who constituted the British X-Ray Unit Committee appointed in 1923, should form a group to nominate the international committee: Sir William Bragg (Chairman), Professor F. L. Hopwood, Dr. E. A. Owen, Mr. C. E. S. Phillips, Professor A. W. Porter, and Professor Sidney Russ.

Silvanus Thompson Memorial Lecture

In the course of the Congress the eighth lecture in memory of Silvanus Thompson, founder of the Röntgen Society, was delivered by the Duc de Broglie, the well known French physicist, who is a doctor honoris causa of the universities of Oxford and Leeds. His general subject was the absorption of x-rays and gamma rays and the secondary rays which accompany them. The lecture was a review of recent work and a description of the lecturer's own investigations on x-ray absorption spectra. He said that it was now possible to begin to describe a definite wave-length to the gamma rays, the absorption of which resembled closely x-ray absorption, with certain differences, however, which were very curious to observe in the cloud-expansion apparatus, and might perhaps help eventually to explain the difference between the observed effects of the two radiations. In the concluding part of his lecture the Duc de Broglie suggested that there might be a kind of "trigger" effect of radiation on living cells. On these deep problems ignorance had to be confessed, but there was little doubt that the joint efforts of biologists and physicists would sooner or later cause some ordered conceptions to emerge from the present obscurity. A vote of thanks was recorded on the motion of Dr. A. E. Barclay, seconded by Dr. KAYE.

Protection of X-Ray Workers

Dr. G. W. C. KAYE (National Physical Laboratory) opened a discussion in the Physics Section on protective and manipulative methods. He said that although the radiologist was not likely to tempt Providence by foolhardy exposure, he did not always appreciate the results of scattered radiation. Radiation was given off from the body of a person who was being subjected to x-rays, and the scattering produced by the air in the room in the vicinity of the x-ray tube was something like that of the primary radiation. If the scattering was excessive the operator should be behind a screen or wall. Each outfit should be protected by walls extending from the floor to the ceiling, and floor and ceiling should also be protected. The protecting lead for a strength not exceeding 70,000 volts should be at least 1 mm thick, and for 100,000 volts 2 mm thick. There was a danger in using gamma rays to test the protection of materials, as these made the protection appear much better than it actually was. All protective boxes should be tested for leakage. He was surprised that the open bulb was still being used, as in many cases it was often possible to take a radiogram of the hand in any part of the room. Generous ventilation of the x-ray rooms had an importance second only to that of protection, and nausea, floor space should be adequate, and the material should be wood, cork, or rubber. M. PIRON (Paris) spoke on the same subject, and described an oil-immersed tube, of the same size as the

Coolidge universal tube, which could withstand 200,000 volts on the direct current. Every part of the glass wall was cooled and had the same temperature. After the box was earthed the patient ran no risk of receiving an electric shock. Mr. V. I. PIRNIS (director of radiological research, Woolwich), who said that he had to do with x-ray protection in fifteen service hospitals, laid stress on the need for efficient ventilation. He also related an instance in which several patients in a ward above an x-ray room had ulcer on the heel after leaving hospital, these lesions were undoubtedly due to radiation having reached them through the ceiling.

The Organization of a Hospital Radium Service

Professor L. L. HOLLOWAY (St. Bartholomew's) described the organization of a hospital radium service. The radium of which he was in charge was distributed among 220 containers. He illustrated the various holders, thermometers, and magnifiers for reading identification marks on the needles—all conceived to avoid handling the radium—also the ingenious drawers, lead encased, in which radium was kept. He submitted a list of the regulations operative in the hospital. Dr. G. FAIRLIE (New York) said that in his hospital colour was largely used for identifying tubes at a distance, and in that way no open wounds resulting from the manipulation of radium had to be dealt with, though the fingers, especially around the nails, became red and scaly.

Exhibition of Apparatus

During the four days of the meeting an excellent exhibition of apparatus and accessories associated with x-ray work and electrotherapy was held at the Central Hall, to which over thirty firms contributed.

THE CONGRESS DINNER

The Congress dinner was held at the Hotel Cecil Central on Thursday evening, under the presidency of Mr. C. THURSTON HOLLAND, who was supported by Sir Humphry Rolleston, F.R.C.P., Dr. E. M. Callender, President of the Medical Society of London, Sir Robert Jones, Sir Dawson Williams, and other members of the Committee of the Congress and the officers. Representatives of seventeen countries were present.

The President recalled the early days of Roentgen's epoch-making discovery, less than thirty years ago. Soon after the discovery was announced the speaker became possessed, through the generosity of his great friend, Robert Jones, of a complete x-ray apparatus—cost outfit—coil, tube, tube stand, and electrical supply—less than £30. Nowadays a young radiologist, if he desired to practise all the branches and to the full extent, would require an outlay on instruments of approximately £3,000. The early work on radiology was done by a band of youngish men, all comparatively unknown in medicine and surgery, who had to fight to a large extent against prejudice, and to wait a considerable time before they were able to establish radiology as a means of diagnosis—to say nothing of treatment—in the position it now held. But what would medicine and surgery be at the present day without radiology? Many of that band of youngish men had suffered physically, some had lost their lives. Quite recently radiology had had to mourn some great figures whose lives might have been prolonged had their enthusiasm been less—Leonard of Philadelphia, Albert-Schönberg of Hamburg, Beigomio of Bordeaux, and in this country Archibald Reid. To-day it was possible for a young man to start on a career of radiology without taking any of these risks, what was more, he could start with the advantage of the knowledge that the older men could impart. He could take diplomas in radiology at two universities—Cambridge and Liverpool—and soon he would be able to take a diploma at a third—Edinburgh. Nevertheless, the speaker did not envy the young men. It would not be theirs to know the thrill of discovering for the first time a stone in the kidney, or of seeing as a novel thing the outline of the stomach under the opaque meal. Yet, no doubt, there was much still to be done, perhaps only the threshold had been reached, and if such congresses as the present were to be repeated, and such work had a joy which money-making could not give. The President concluded

with a tribute to some of the men behind the Congress—to Dr Robert KNOX, the moving spirit, the Presidents of the three co-operating bodies, Dr Barclay of the Roentgen Society, Dr Melville of the Electro-Therapeutic Section of the Royal Society of Medicine, and Sir Humphry Rolleston of the British Institute of Radiology, the honorary treasurer, Dr James Metcalfe, and the joint secretaries, Dr J. E. A. LANHAM and Dr John Muir.

Delegates from the different countries then expressed, most of them in one or two sentences, their appreciations.

Professor C. BÉCLÈRE, speaking in French, after an eulogy of the organizers of the Congress, referred to the appropriateness of the portrait of Roentgen on the dinner card. He said that this was an act of justice and of gratitude, a proper homage to the intellect of the scientist and the character of the man. What portraits might accompany that of the great Roentgen at future Congresses? He hoped those of Henri Becquerel and the Curies, whose discoveries had opened a new domain to radiology. Such a group would be an eloquent symbol of the intimate bonds which united great discoverers, and a testimony to the fact that this science of radiology, like other sciences, was a collective piece of work, an achievement to which men of many different countries contributed—here and there a man of genius, but also, not less to be regarded, a multitude of modest workers animated by the same spirit. It was essential that the co-operation in science of men of different nations should become closer, more active, and more powerful. One of the necessary conditions for the progress of radiology was the *entente* between radiologists of all countries.

Professor HANS DIETLEN, speaking for German radiologists, said that internationalism had always been a necessary condition of effective culture, and his countrymen were grateful for the opportunity of participating in this gathering.

Professor M. NEMENOV (Russia), who spoke in German, said that the Russian delegation came from a far country after a political earthquake, and were hardly sure of their reception, but it was enough for them to exchange the first few words to know that they were in hospitable company.

Professor CARL SONNE (Denmark) said that his country was the first to place actinotherapy on a firm scientific basis, and he was glad to find actinotherapy represented by a section in the Congress. Dr L. F. DRIESSEN (Holland) said that he spoke for a small country, but he was glad to point to the disproportionately large attendance of members of the Dutch Roentgenological Society, of which he was president. Professor GÖSTA FORSSELL (Sweden) said that the Congress was a model to all future international meetings, but those who entertained subsequent Congresses would be hard put to it to reach the high level of British hospitality. Dr P. M. HICKES (United States) presented the felicitations of American radiologists on "pulling off" such a wonderful Congress. If the statesmen and editors of the world would take a lesson in brotherly love from the scientific men the troubles of the world would very soon be straightened out.

Others who responded more briefly were Dr CARLOS HEUSEN (Argentina), Professor A. SCHÜLLER (Austria), Professor DE NOBELE (Belgium), Dr HOWARD PIRIE (Canada), Dr W. ALTSCHUL (Czechoslovakia), Dr M. PONZO (Italy), Mr M. R. J. HAYES (Irish Free State), Dr S. A. HEYERHAEL (Norway), Dr J. DEBICKI (Poland), and Dr R. FEISSLY (Switzerland).

MACKENZIE DAVIDSON MEMORIAL LECTURE

The Mackenzie Davidson Memorial Lecture, held under the auspices of the Electro-Therapeutic Section of the Royal Society of Medicine and the Roentgen Society, was delivered by Sir BERKELEY MOYNIHAN on Friday evening before a very large gathering. Among those present was Lady Mackenzie Davidson. Sir Berkeley Moynihan's lecture on "The relationship of radiology and surgery," is printed in full at page 47 this week.

Dr STANLEY MELVILLE proposed, and Dr A. E. BARCLAY seconded, a vote of thanks to Sir Berkeley Moynihan, and Mr THURSTAN HOLLAND, who presided, presented him with the Mackenzie Davidson memorial medal amid much acclamation.

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS

ELEVENTH ANNUAL CONFERENCE

THE eleventh annual conference of the National Association for the Prevention of Tuberculosis was held at the house of the Royal Society of Medicine on July 6th and 7th, under the presidency of Sir ARTHUR STANLEY. The proceedings were opened by Sir KINGSLEY WOOD, M.P. (Parliamentary Secretary to the Ministry of Health), who expressed official appreciation of the work of the association and of its character as a voluntary body.

Visitors were present from the United States, Denmark, Austria, and Russia. The Russian representative, Dr VONEBELFF (Moscow), said that the health of the Russian population was rapidly improving, and the campaign against tuberculosis was now organized on a large scale. The propaganda found successful in England was being followed, and the people were encouraged to active participation in health work. Dr WOODS HUTCHINSON (United States) spoke eloquently on the decline of tuberculosis as a result of sanitary skill and enlightened public opinion.

Sir ARTHUR STANLEY said that the association, responding to a suggestion made at the last conference by the late Minister of Health (Mr John Wheatley), had drawn up a memorandum on the establishment of model workshops for the tuberculous community, but owing to the change of Government and the pressure of public work the matter was in abeyance. The propaganda of the association had gone steadily forward. A vote of thanks to Sir Arthur Stanley for his services as chairman of council was recorded on the motion of Sir ST. CLAIR THOMSON, seconded by Sir HUMPHRY ROLLESTON.

Tuberculosis in Childhood

Two subjects were before the conference, one of them "Tuberculosis in childhood," and the other "The treatment of tuberculosis by sanatorium." Professor PIQUET had been announced to open the first of these discussions, but owing to illness in his family he was unable to leave Vienna, and his paper was read by Dr Richard WAGNER, of the children's clinic in that city. Professor PIQUET made use of the statistics of the Registrar-General for England and Wales to show the enormous significance of tuberculosis as a cause of mortality at the most efficacious period of life. It appeared to assert itself as the chief mortal disease from the age of 10 up to the age of 46. Dr WAGNER also read a paper of his own, on the nutritional treatment of tuberculosis in childhood, in which he gave some statistics of the morbidity from this cause in Vienna and Lower Austria. He described also the nutritional classes at the children's clinic, and the results which followed.

Dr A. STANLEY GRIFFITH dealt with the bovine tubercle bacillus as an important source of human tuberculosis. The highest percentage of bovine infections was found in children under 5 years of age. It would be difficult, though not impracticable, to free the whole country from bovine tuberculosis, but until the ideal of tubercle-free herds was attained universally all milk not from such herds or not efficiently pasteurized should be sterilized in the home before being given to infants, children, or sick persons. As to the objection that bovine tubercle bacilli in milk might confer an immunity to the more dangerous human infection, he thought there was no evidence that the absorption from the alimentary tract of small numbers of bovine bacilli had any significant or lasting immunizing effect. Dr C. RIVIERE said that in modern civilized communities repeated infection with the tubercle bacillus was inevitable. This infection led to immunity and protection against the disease. The primary infection was of importance, and probably determined the whole future *qua* tuberculosis. Infection in early infancy was dangerous and postponement was valuable, but could only be temporary. The infection might be with the highly virulent human strain, commonly by the air passages, or with the bovine strain, comparatively innocuous to man, by the alimentary tract. Was it worth while to withhold this latter source of infection knowing that the alternative was the dangerous

human type of the bacillus? Nevertheless, he hoped that some day public opinion would be ripe for a less clumsy procedure of tubercle immunization than the giving of milk.

SIR ROBERT PHILLIP spoke of the lines on which preventive treatment of the child had proceeded of recent years. The Giancher method, by which delicate children were transferred from dubious home environment to presumably healthy surroundings in the country, was subject to the fallacy that most of the children thus taken in hand were already tuberculous, and the excellent results following the system were to be attributed to a progressive detubercularization along natural lines. Another proposal was that prior to "spontaneous" infection the child should undergo artificial inoculation in order to anticipate the effect of exposure, but it had yet to be seen to what extent, in the absence of disease, parents would consent to submit the newly born infant to inoculation with tubercle bacilli, however modified, and however simple the process might be. His own plan of "anticipatory detubercularization" proceeded on the assumption that infection took place practically always during childhood, that the occurrence of the subsequent process of tubercularization might be definitely determined, and that it was possible to limit and counter the process by detubercularization. His method had two aspects—environmental and antigenic. The results had been described by him in the *BRITISH MEDICAL JOURNAL* (March 24th, 1923).

Among other speakers Sir WILLIAM THOMPSON referred to the drop in child mortality from tuberculosis during recent years in the Irish Free State, Dr FRANCIS HEWITT related some experiences from the Edinburgh Royal Infirmary, and Professor LOUIS McLEOD dealt with the provision for infected pregnant women.

On the second day of the conference, with Sir ROBERT PHILLIP in the chair, the discussion was continued, and Sir HERMAN GAVARIN gave an address on the prevention, treatment, and after-care of surgical tuberculosis in children. He refused to believe that bovine tuberculosis could not be relegated to the horrors of the past. The argument that drinking slightly infected tuberculous milk would enable one to acquire immunity to infection he described as a dangerous and unnecessary doctrine. Dr GORDON PUGH followed with an illustrated description of the constitutional treatment of early non-pulmonary tuberculosis as carried out at Queen Mary's Hospital for Children at Carshalton, and showed the special spinal and hip frames and carriages designed to facilitate the application of heliotherapy, arc-lamp treatment, and gymnastic exercises, while immobilizing the diseased part. Professor JOHN FRISER referred to the relative incidence of surgical tuberculosis among town and country children. In Scotland the disease was more frequent among dwellers in the country. In the cities the organization of milk inspection was thorough, in the country it was too often a dead letter.

After some general discussion the conference unanimously passed resolutions urging the Government to use every possible means to render effective all the provisions enacted in the Milk and Dairies Acts of 1914 and 1922 and the subsequent regulations, also asking the Ministry of Health and the Board of Education to consider the desirability of including in school education more definite instructions regarding the principles of health conservation, personal and communal, and simple methods for the prevention of tuberculosis.

The Sanoerysin Treatment

The final session was concerned with the treatment of tuberculosis by sanoerysin, and was almost entirely occupied by lectures, each of an hour's duration. Professor HENRI MOELLGAARD of Copenhagen recapitulated the principles and results of the treatment, as set out in his recent article in these columns.¹ He added that up to the time he wrote his paper he believed that sanoerysin had no influence on surgical tuberculosis, but some evidence had come before him during the last few days that in suitable doses it was effective here also. The results of his

veterinary experiments had been supported by some recent researches made in the Danish State Serum Institute, and reported by Dr MADSEN in May last.

Dr KARL LARSEN (Professor of Clinical Medicine, Copenhagen University) described experiences with sanoerysin treatment during the last seven months in the university clinic. Before coming to the results he dealt with the reactions and dangers of the treatment. The treatment resolved itself into a short series of injections, the effect of which on the patient's temperature diminished with each injection. The greatest risk was the occurrence of the acute stage of shock described by Professor MOELLGAARD, the shock was most likely to occur when the injection was given while the patient still had fever reaction from a previous injection. The danger of the treatment really consisted in following the injections too rapidly upon one another, with consequent accumulation. He advised a less intensive treatment than the one originally proposed, so that the harmful effects might be reduced and controlled. In grave febrile cases it was necessary to be particularly cautious. Dr LARSEN then showed charts and x-ray photographs relating to a small number of cases of pulmonary tuberculosis in which a decidedly favourable effect of the compound was seen. Apart from improvement in the general condition—the cessation of the febrile or subfebrile state—there were certain objective changes, particularly the disappearance of rales, freedom of the expectoration from bacilli, and improvement in the x-ray picture. The material was as yet too small and heterogeneous for conclusive statistics to be furnished, but an estimate was possible in about 40 cases coming under his own observation in which the treatment was finished or almost finished. Eight of these patients must be regarded as clinically cured, 17 showed very considerable improvement, 9 still showed signs of active phthisis after six months' treatment, and in 6 patients the disease had not been arrested at all, but rather had tended to spread. The best results were obtained in patients who had been suffering for less than a year from the illness. During the last twelve months the treatment had been employed in Danish sanatoriums, and here the statistics, relating to 250 cases in which the treatment might be said to be finished, showed decided improvement in 52 per cent. It was still too early to give a pronounced and final verdict, but it seemed to him that the compound was able to bring about in many patients a pronounced and rapid improvement not obtainable by any other method.

Professor EILE CURRIE said that his experience had been confined to eight selected cases. All the cases had done well, and the improvement had been so much more rapid and dramatic than was to be expected in cases of this type that he was unable to avoid the conclusion that sanoerysin was the favourable factor in each. These eight cases had impressed themselves on his mind more sharply than a far larger number of cases in which other recent methods had been tried. All the cases at first lost weight under treatment, and all experienced severe reactions at the beginning, but, on the other hand, the weight was rapidly regained after the inoculations, the cough diminished or disappeared, the sputum in several of the cases disappeared or showed a great fall in bacterial content, and some improvement was noticed in the x-ray picture. The use of serum was definitely helpful in the control of albuminuria, but it had its own inconveniences. He had found it useful to space the doses rather more widely than was originally advocated by Dr SEECHER during his visit to London in December last. The speaker believed that the use of sanoerysin should be safeguarded, not so much by reducing the dosage as by selecting patients with tuberculous lesions of relatively small extent. He thought that this treatment should not at present be handed over to general practice, but should be carried out by specialists at special hospitals.

SIR ROBERT PHILLIP said that the Medical Research Council was hard at work to determine whether, on the one hand, the experimental process advanced by Professor MOELLGAARD was sound, and, on the other, whether and to what extent the results brought forward could be corroborated by further results.

SATURDAY, JULY 11TH, 1925

INTERNATIONAL RADIOLOGY

THE Congress of Radiology in London last week may be considered to mark the coming of age of radiology as a special department of medicine. It is true that it is thirty years since Roentgen made his discovery bringing to the point of utility a series of researches which had been prosecuted in a rather desultory way by physicists in this and other countries. But some few years elapsed before it was realized how great were the services the discovery might render to various arts, to none have they been so great as to medicine. The conference was not summoned as an International Congress, but it was attended by representatives of the specialty in many countries, who quickly voted with unanimity that it should be recognized as the first International Congress of Radiology.

If the Congress marked the coming of age of radiology, it was Sir Berkeley Moynihan who made the birthday speech in his Mackenzie Davidson Memorial Lecture which is published in full in the opening pages of this issue. That the lecture should have been delivered during the first International Congress of Radiology was most appropriate, for Davidson, then at Aberdeen, was one of the first to take up the new method seriously, to equip himself with the best apparatus available, and to be satisfied with nothing but the best results then possible to be obtained. Afterwards he removed to London, and, by his ingenuity in devising apparatus, his energy in trying new methods and the enthusiasm with which he preached the new doctrine, did in the early days more, perhaps, than anyone in this country to establish its practice on sound lines. The choice of the orator also was fortunate. Sir Berkeley Moynihan's powers of lucid exposition are unrivalled, and no surgeon of the future will be in quite so good a position to describe the greater accuracy of diagnosis which is owed to radiology, for he has watched its development and himself experienced the steady increase in the value of the information it can afford. Emphasis must be laid on the word 'can,' for, as he insists more than once, the radiologist must be allowed time enough for his study of the case if the full advantage of all that he can do for the surgeon is to be obtained. It will not do merely to direct that an x-ray examination must be made, the surgeon—or, for that matter the physician, whether doomed to be a surgeon or not—should consult with the radiologist. If this were always done it would prevent misunderstandings and would incidentally reduce the activities of the non-medical radiologist, a reform for which there is need. Emergencies apart, what the surgeon ought to say to the radiologist is "Examine this case thoroughly, using all the methods at your disposal, and then tell me and show me the evidence you have collected, giving me your judgement on its significance."

Sir Berkeley Moynihan confined his survey to the alimentary canal, going beyond it only to make a brief reference to the urinary tract. Even so, he had a very wide field from which to gather his harvest, and he brought in many sheaves, for, much as radiology has

done to make diagnosis more accurate in diseases and injuries of the head, the chest, and the limbs, it has done more, with the possible exception of the last named, for the abdomen. He did not stint his praise. Speaking of gastric diseases, with special reference to ulcer, he proclaimed that it was hardly too much to say that we owe almost everything to the radiologist, the accuracy of the radiologist in the diagnosis of gastric ulcer nearly approaches that of the surgeon who, with the abdomen open, inspects and handles the stomach. Of what used to be called idiopathic dilatation of the oesophagus, now known as cardio-sprism, we could, he said, "know nothing accurately apart from the examination made by the radiologist." Again, he observed that the recognition of diaphragmatic hernia "without the aid of radiology is excessively difficult or perhaps impossible." Passing to the diagnosis of diseases of the gall bladder, he said that in cholelithiasis radiology enables a diagnosis to be made which otherwise would be in doubt, it discovers associated lesions in neighbouring viscera, and is an instrument of research into the composition of stones, and may so throw light on their formation.

But, though he was generous in recognition Sir Berkeley Moynihan discussed quite frankly the limitations of radiology, directing attention in particular to gastric ulcer and cholelithiasis. His observations should be read in full, but a not unfair summary would be that a positive report from the radiologist is of far greater value than a negative, and that where a negative report is opposed to the impression produced on the mind of the surgeon by all the clinical evidence taken together it should be disregarded. Perhaps here we have light thrown on dark words he used at the beginning of the lecture when he described himself, not for the first time, as "a physician doomed to the practice of surgery." Others, perhaps, would gladly accept the doom without repining, but the phrase was something more than a jest. It meant, we suspect, that everyone must, before all things, strive for the highest attainable accuracy of diagnosis, and must neglect no means to that end before resorting to the knife—that the day of the "look and see" surgeon has passed. He was careful to insist that once the diagnosis has been made as precise as possible there should be no delay in acting upon it. This is one of the observations that make the lecture of so great value to the general practitioner. Before closing Sir Berkeley Moynihan spoke shortly of therapeutic applications of radiology, and referred to a method he has tried in carcinoma of the stomach—that of opening the abdomen and exposing the organ for forty minutes to x-rays under a single layer of macintosh gauze. In two cases in which this method was used the results proved decidedly encouraging for when the abdomen was opened again seven and nine weeks later the growths were so changed and shrunken that it was possible to remove them with all their attached glands. Reports of future experience with this method will be awaited with particular interest.

The verdict of all who attended it is that this first International Congress of Radiology was a great success. Foreign members praised the way in which it was organized; the credit is in large measure due to Dr Robert Knox, chairman of the Organizing Committee who was described by Mr Thurstan Holland at the dinner as the moving force behind the whole project, Dr Stanley Melville, secretary-general, and the joint secretaries, Dr Lynham and Dr Muir, upon whose shoulders, as secretary of the British Institute

of Radiology—the headquarters of the Congress—a great deal of the preparatory work fell

The Congress was international, no nation was excluded, and twenty-two, we are told, were represented. It had several set discussions and saw some striking demonstrations, but the number of papers in the three sections was so large that time to debate them could not be found. Following our preliminary notice published last week, the work of the Congress is reported at some length in this issue (p. 67). The full text of all the papers will, we are told, eventually be published in the *Journal of Radiology*.

Before separating, the members decided by a unanimous vote that the next Congress shall be held in Sweden three years hence; it was to be noted at the dinner that no speaker was received with applause so warm as the leading representative of that country, Dr. Forssell, who seemed to personify for his brother radiologists the spirit of international amity the Congress was designed to promote.

THE CIVIL RESEARCH COMMITTEE.

We gave last week (p. 25) some particulars of the Treasury minute defining the functions of the new Committee on Civil Research and of the Lord President of the Council's speech indicating the objects with which it has been set up. Lord Balfour described the new Committee as "an additional wheel required to complete the mechanism of Cabinet government," and he specified three directions in which the services of this new Committee would at once be available—namely, in co-ordinating the work of different Government departments, in tackling special problems, and in securing the counsel of the Dominions.

Health questions have suffered as much as, if not more than, other questions from our present ill-co-ordinated system of administration. Such problems as hookworm disease, sleeping sickness, yellow fever, plague, and bilharzia are international, and demand co-operation between neighbouring countries. It may be difficult to secure this co-operation if rival Governments must first be consulted, but within the British Empire co-operation should be possible of achievement. Nevertheless, our present system of administration offers insuperable difficulties, as all reformers in imperial hygiene know only too well. Thus, all medical problems in India are handled by the India Office, and those of Ceylon by the Colonial Office. Hence, under existing arrangements the much needed campaign against hookworm disease would be superintended by two separate organizations, each with its own traditions, and each jealous of any infringement of its rights. A traveller returning from a tour of the Empire would find it difficult to discover which Government department, if any, supervised the health questions which seemed to him so pressing in different parts of the Empire. The Foreign Office, the Colonial Office, the War Office, the Air Ministry, the Admiralty have each established areas of authority, the self-governing Dominions are, of course, entirely independent in such matters, so that the means they are taking to tackle their health problems come only unofficially to the notice of the central seat of government. In the face of such a complicated and unco-ordinated system, small wonder that no bold attempt is made to attack problems of imperial health.

Health matters are, we understand, among the first which the new Civil Research Committee proposes to study, and the particular question of co-ordinating

medical services throughout the Empire is worthy of the first claim on its attention. Its elastic nature should enable this Committee to cope with almost any question, for it would appear that the only permanent member of the Committee is the Prime Minister, though the Minister nominated by him to act as chairman will, it may be assumed, act in that capacity continuously for a considerable period, if not for the lifetime of the Ministry. For any particular subject to be discussed the chairman (or the Prime Minister) will call together a committee of experts. It may perhaps be assumed that there will be committees dealing with shipping, trade, foodstuffs, agricultural problems, mining and many other questions which require the co-ordination of different Government departments.

In its working the new Committee will not be hampered by rigid rules. The Treasury minute lays it down that the Civil Research Committee shall be an advisory committee without administrative or executive functions. Lord Balfour, in laying stress on this, said that it would be modelled on the Committee of Imperial Defence, which was established some twenty-five years ago to co-ordinate the work of the army and navy and to consider all questions connected with the defence of the realm. In referring to the advantages which flowed from the work of this body he remarked that a valuable characteristic of the Committee of Imperial Defence was that it could not give orders to anybody, instead of increasing friction between departments and causing jealousy against itself in the minds of departments, it was of inestimable value in making all the departments work as parts of one machine. We imagine, then, that health questions which have been discussed by the Civil Research Committee, often, probably, together with representatives from different Government departments and from the Dominions and Colonies, will be referred back by the Cabinet to the home departments concerned, and, if the Committee's deliberations have pointed to any practical measures, it will bring pressure to bear on each department to see that these are executed, and will satisfy itself that they are executed.

So far we have spoken only of the more efficient working of the machinery of State as already established, but we think we detect in the establishment of this advisory body something more than a touch of lubrication of the wheels of government. We hope we may discern beneath the argument of expediency official recognition of the principle that henceforth human life must be guided by science. Nearly all the necessities of life are brought to this small island from distant lands, and a watchful eye must scan the activities of far away fields. In our peculiarly vulnerable position foresight alone can protect us from dangers threatening ahead, and for this peering into the future we shall need the help of every instrument of science. The Civil Research Committee will, we hope, not only possess the seeing eye, but also the co-ordinating brain. Certainly we need both these faculties in all the big health problems of the Empire.

THE Royal College of Surgeons of England will give a reception at its house in Lincoln's Inn Fields on Monday evening, July 13th, in connexion with the Convention of English-speaking Ophthalmological Societies. Fellows and Members of the College wishing to attend are asked to apply to the Secretary of the College for cards of admission.

AN EXHIBITION OF SPECIMENS

During the present month a special exhibition of specimens is to be seen in the museum of the Royal College of Surgeons of England, Lincoln's Inn Fields. The specimens shown represent additions and donations made during the past twelve months, and many of them are of exceptional interest. One hundred and seventy of these new specimens are of a pathological nature, and have a direct bearing on problems which are now occupying the attention of medical men. Especially numerous are the preparations which illustrate lesions of bone. The visitor's eye is at once attracted by a series which was presented to the College by the executors of the late Sir William MacEwen, and represent the results obtained by that great surgeon during his experimental inquiry on bone growth. Sir William often visited the museum of the College to study Humerian specimens, particularly those which illustrate the manner in which bones grow, and had expressed a wish that his own might be added to the Humerian series. A valuable addition to the same series is made by Mr. I. W. Hey Groves. It is evident from the number of specimens of myeloma in the neighbourhood of the knee-joint that this form of tumour is engaging the attention of surgeons. Visitors to the exhibition have an opportunity of satisfying their curiosity as to the nature of the ailment which so disfigured the face of a chimpanzee, known as "Mick," which lived in the ape house of the Zoological Gardens for twenty-seven years. His muzzle became massive, and two horn-like bony excrescences arose at each side of his nose—very similar to the condition seen in the "horned" men of West Africa, a condition now described as frambesial osteitis. The skull of "Jelly," who was also in the Zoological Gardens for many years, is also exhibited, and shows a less marked degree of the same disorder, evidently one which results from some form of slow infection. A striking feature is the massive growth of the alveolar bone of the jaws, with an arrest in the eruption of the permanent teeth. The exhibition contains also some delicate dissections which illustrate points in the finer anatomy of the thyroid and other glands of internal secretion of lower vertebrates. For these Mr. R. H. Burne, physiological curator, is responsible. Of especial interest are the preparations which show the peculiar system of lymph vessels which are connected with the thyroid gland of *Lophius*, the angler fish. Many additions have been made to the craniological and other series in the museum. The exhibition is open to all medical men between the hours of 10 and 5, except Saturdays, when the museum closes at 1 o'clock.

"GOUNDOU" HORNE MEN IN AFRICA

The nature of the osseous tumours involving the infra-orbital ridges of the maxillary bones in a case of the condition, referred to in the preceding paragraph as that presented by the horned men of West Africa, was described to the Royal Irish Academy by the late Professor Alexander Macalister in 1882 and 1883. In 1887 Surgeon J. J. Lempriere, of the Army Medical Staff, described in our columns three other cases of this condition, which is well known on the Gold Coast under the title of "henpuye" or "dog's nose," and on the Ivory Coast as "n'goundou," from which its more common designation of "goundou" is derived. Other accounts of this disease were contributed to this JOURNAL by H. Strickland and J. O. Shucrore. Major Botreau-Roussel, of the French Colonial Army, has now published a book on "goundou," based on his observations on the

Ivory Coast between 1912 and 1917, when he collected 130 cases and operated on 113 patients. He claims to have established that this condition is only one symptom of an hypertrophic osteitis affecting several bones and sometimes involving the greater part of the skeleton. He maintains that it is always secondary to tropical frambesiosis. Professor Cornil of Nancy has shown that the lesions are not tumours in the pathological sense of the term, but are due to inflammatory osteogenic hyperplasia comparable with that occurring in syphilis. Dr. J. N. Roy of Montreal, who was associated with Major Botreau-Roussel in 1912, and has himself observed thirty-four cases, contributes an article to the *Revue de Laryngologie, d'Otologie et de Rhinologie*, in which he disagrees with the view that this condition is due to frambesiosis, or to a lesion of the central nervous system, or to syphilis, or to insect bites. Roy has found spheroidal bodies 25 to 30 μ in diameter in these tumours, and is of the opinion that etiological significance is to be attached to them. While admitting that goundou and yaws are often associated, Roy insists that there is no real connexion between the two diseases. Botreau-Roussel, however, in support of his contention points out that in 103 out of his 130 cases frambesiosis either accompanied or preceded the development of the osteitis, the bone lesions appearing in 98 cases during the eruption or immediately afterwards. He also emphasizes the importance of the fact that the pathological processes in the bones are similar to those in syphilis and frambesiosis. In one case the bone lesions and the skin eruption yielded simultaneously to treatment by novarsenobenzol. The disease is far more widespread than was originally believed, and Roy has collected evidence of its occurrence in the West African littoral, Zanzibar, British East Africa, the Malay Peninsula, the East and West Indies, Southern China, Honduras, Mexico, and Brazil. He mentions an instance of the disease being contracted by a European who had lived on the west coast of Africa for twelve years, and reports the discovery of a skull of a 7-year-old child, found in an Inca grave in Peru, which presented the typical aspects of the condition. The bony growths are usually bilateral, and develop on the nasal bones or on the ascending process of the superior maxilla; these bones may be invaded simultaneously. The disease may become generalized, exostoses forming on nearly all the skeletal bones. The disease occurs usually during early childhood, but is often observed in adults, and is possibly a little more common in males than in females. Botreau-Roussel illustrates his descriptions with a large number of photographs and radiographs, and appends a good bibliography.

A RESEARCH INSTITUTE FOR KENYA

Not long before his tragic death at Nairobi last February the late Sir Robert Coryndon, Governor of the Colony, had expressed himself strongly as to the need for a museum and library devoted largely to the study of natural history and its allied sciences in Kenya Colony, a proposition that has met with the universal approval it deserves. It has been felt in the colony that the services of Sir Robert Coryndon were of the greatest value to Kenya, and it is proposed to build a memorial to him at Nairobi in the form of a hall or the wing of a building to bear his name and form part of a larger museum or institute for the advancement of the natural sciences on the progress of which the welfare of the colony depends. There is at present in Nairobi a small but admirable Natural History Museum, full of merit so far as its restricted resources have permitted its development and receiving some small measure of support from the public purse. It was Sir Robert Coryndon's idea that this museum should be enlarged and extended in connexion with a library and an institute for the undertaking of research, and he

⁴ *Osteites l'antiques (Goundou)*. Par Botreau-Roussel. M. le Dr. Major de Ire Classe des Troupes Coloniales. Collection de la Société de Pathologie Exotique. Paris. Masson et Cie. 1925 (Roy. 8vo pp. 129 69 figures. Fr. 16)

particularly mentioned veterinary and botanical research as called for at the present time. An appeal was issued from Government House, Nairobi, last March, asking for subscriptions to the Corindon Memorial Fund, and this appeal has met with a considerable amount of support locally. It has now been brought to the attention of a wider public, and it may here and now be recommended to the notice of readers of the *BRITISH MEDICAL JOURNAL* as an appeal for funds for an object that is entirely deserving. Sir Robert Corindon had some five and thirty years of experience as an administrator in South Africa and Kenya Colony. He recognized that vast areas of fertile land in the African continent are closed to human enterprise by disease and by the insect carriers of disease that render them uninhabitable for working man and domestic beast alike. He knew that it is to science—bacteriological, entomological, veterinary, and so forth—that we must look for the key to these areas, if they are to be rendered fit for human habitation, whether black or white. To those interested in the population of tropical countries it has long been, indeed, a platitude that the man of science is even more indispensable to the administrator in the tropics than he is in less torrid climates. The fact is known, and, what is more, is acted upon nowadays by our politicians and our statesmen, and was emphasized only a week or two ago by Mr Oimsby-Gore when addressing the Imperial Entomological Conference. As was perhaps natural in the circumstances, Mr Oimsby-Gore eulogized the horn of the administrator in this partnership of government and science. So, too, does the writer of a leading article on "Science and administration" in the *Times* of June 20th, who describes the modern co-operation between statesman, entomologist, bacteriologist, botanist, veterinary surgeon, and medical man in the enterprise of tropical sanitation adding the words "But the part of the statesman is the greatest, because if he fails complete disaster is assured." It is always an ungrateful task to attempt to assess separately the values of the work performed by the hand and the head acting together, although we cannot help thinking that it has been done by some noted fabulist. At any rate, the teaching of experience shows that the plucking of a sleeper across the rails by a naughty child can assume complete disaster to the best train in the world.

THE SANITARY CONDITION OF BARGES

DURING recent years the annual reports of the Registrar-General for England and Wales have provided evidence of the unhealthiness of the occupation of barges and lightermen. Thus in the period covered by the three years 1910, 1911, and 1912 the comparative mortality figure was 1,102, which compares very badly with 790 for all occupied males, of 470 for the open-air occupation of farm labourer, and of 838 for what one might conceive to be the like occupation of fisherman. These facts are commented upon by Dr Dearden in that part of the annual report of the medical officer of health for the Port Sanitary Authority of Manchester which deals with the sanitary condition of ships (pp 39-52). He points out that although amongst bargemen and lightermen there is an excess of liability to fatal accidents, as shown by the mortality rate of 193 against the average one of 49, yet this is insufficient to explain the high mortality figure. Excessive liability to respiratory diseases, particularly pneumonia, is the cause of the high mortality of bargemen. The fisherman whose record shows the effect of a strenuous life equally with that of the bargee, is in a totally different class when respiratory diseases are taken into account. The liability of the bargee to die from phthisis is the same as that for all male workers, as the figures quoted in Dr Dearden's tables show, but these tables, which compare the mortality of bargemen, fishermen, farm labourers, and occupied and retired males, reveal

the fact that the mortality of bargemen from pneumonia is almost twice, and then mortality from bronchitis more than thrice, that of fishermen. The mortality of bargemen from respiratory disease of all sorts is more than twice that of fishermen, and three times that of farm labourers. The occupation of bargee is one that should be favourable to good health, since it is carried out in the open air and involves a considerable amount of muscular exercise, but Dr Dearden's investigations have convinced him that the real reason for this excessive mortality from respiratory disease is to be found in the evil influence of the housing conditions on these boats. On one occasion during the year under review a company was prosecuted by the health authority for a nuisance existing on a barge, the offence being dampness of cabin and bedding owing to rain water and river wash penetrating through the scuttle hatchway. The magistrate decided that no nuisance had been proved and dismissed the summons. This decision must discourage a firm policy of reform.

EPIDEMIC HICCUP

DURING recent years the occurrence of epidemics of hiccup have been reported from time to time, and the etiology of this condition has attracted considerable attention. Dr I. T. Cadham of Winnipeg has recently published an account¹ of the three Winnipeg epidemics in 1919, 1922, and 1924. In the first of these epidemics 1,000 cases were reported, the second was on a smaller scale, but in the third a record of 1,400 cases was obtained in a population of a quarter of a million. Each of these epidemics began early in November, reached its height by the beginning of December, and declined rapidly. The great majority of the patients were adults, and more than 90 per cent of the cases occurred in males, no evidence of any racial immunity was forthcoming. In the 1924 epidemic four patients reported that they had had a previous attack in 1919, and two other patients had had a previous attack in 1921. All agreed that the symptoms in the second attack were less severe than in the first, and each patient was cured within thirty-six hours, whereas the previous attacks had lasted more than three days. Cultures from the naso-pharyngeal secretion yielded a streptococcus resembling that isolated by Rosenow, to whose work in this connexion we referred on April 7th, 1923 (p 603). It was considered, however, that no definite etiological factor had been established, though bacteriological investigations are proceeding. Each epidemic was associated with an outbreak of a catarrhal infection of the influenza type, which, however, appeared two weeks later and occurred equally in both sexes. The relation of hiccup epidemics to encephalitis lethargica has been much discussed, in both conditions the difficulty of tracing infection is pronounced. Dr Cadham points out that the first epidemic of hiccup in Winnipeg, in 1919, coincided with the first epidemic of encephalitis in that city, there being 104 cases of encephalitis, with 25 deaths. During the milder epidemic of 1921, 31 cases of encephalitis were reported, and in the winter session of 1922-23 108 cases, though during that time no record was obtained of a single case of hiccup. Three cases of encephalitis during the 1919 epidemic began with hiccup, one patient in 1921 developed hiccup simultaneously with myeloma of the arms, legs, and abdomen, and during the 1924 epidemic one patient suffered from herpes zoster, hiccup, and lethargy, suggesting the existence of a lesion in the central nervous system. Dr W. R. Brain has recorded the case of a patient developing a mild form of encephalitis lethargica after suffering for a month from intermittent brief attacks of hiccup.² He suggests that hiccup is probably a myoclonus of the diaphragm, a view supported

¹ *Journ Amer Med Assoc* February 21st 1925 p 580

² *BRITISH MEDICAL JOURNAL* November 10th 1923 p 806

by Dr M J Chevis, who attributes to it a rheumatic etiology. Dr Cudham believes that myoclonic spasms of the rectus abdominis occurred more frequently in these cases than is generally recognized. A little light is thrown on the difficult problem of infection by Dr L Archer-Brown,² who describes the circumstances attending the onset of the disease in himself during an epidemic in Philadelphia. Other interesting characteristics of this disease are the intermittent character of the spasms, the mild neuritis frequently following hyperaesthesia of the scalp, face, and neck, the slow pulse, and the absence of pyrexia. Various remedies have been suggested, but their value is difficult to estimate. Sedative remedies, including chloroform and morphine preparations, are perhaps most generally used, and protein injections have been recommended, and benzyl benzoate has been found useful.

THE SPAHLINGER TREATMENT

From Parliamentary reports (p. 89) will be found a very full account of the memorandum presented to the Parliamentary Medical Committee by five of its members who recently went to Switzerland to visit M Spahlinger's laboratory near Geneva. The members of the party acted on their own initiative, and the recommendations with which the memorandum concludes are, by request, omitted. The opinion of the committee appears to be divided upon the question whether any action should be taken by it on the memorandum. M Spahlinger is now in this country, and on July 7th met at the House of Commons the five medical members who had made the journey to Geneva. We are informed that an interview between him and Sir George Newman was then arranged for some day next week, and that the Ministry is likely to maintain the position it has taken up all along—namely, that it is willing to give a thorough test to the method provided an adequate supply of serums and antitoxins can be assured. Another interview is to take place between the five members of Parliament and M Spahlinger on Monday to hear from him whether he can assure supplies for the treatment in London of a considerable number, say 1,000, cases of tuberculosis. As will be seen, the memorandum states that the public can entertain no hope of securing treatment by the method at the present time, and that it will be useless for patients to apply. There is, we are told, again talk of an appeal to the public to contribute to a fund to aid M Spahlinger in the preparation of the materials.

THE HONG KONG MEDICAL CONFERENCE

At the invitation and with the co-operation of the Hong-Kong and China Branch of the British Medical Association, the China Medical Missionary Association held its seventeenth biennial conference at Hong-Kong last January. Delegates attended from Great Britain, India, and America, and authorities in different branches of medicine and surgery addressed the conference. By a coincidence the two bodies which met in conference—the Branch and the association—took origin in the same year (1886). In the following year the Hong-Kong College of Medicine was founded, with Sir Patrick Manson as its first dean, and out of this college grew the university and its medical school. The latest issue to reach us of the *Caduceus* (the journal of the Hong-Kong University Medical Society) is a special number, containing an account of the proceedings in the various sections. The conference opened with a congregation of the university in the City Hall, at which His Excellency the Governor of Hong-Kong, as Chancellor of the University, presided, and conferred the honorary

degree of LL.D. upon Drs Philip Conslind, Henry Houghton, Edward Hume, and Ernest Mann. The President of the Branch, Dr G E Aubrey, welcomed the delegates on behalf of the British Medical Association, and read messages, including congratulatory scrolls from the Provisional Chief Executive of the Republic of China and the Vice-Minister of Foreign Affairs, Peking. The *Caduceus* prints English renderings of these picturesque Oriental salutations, the Vice-Minister's message ends thus: "At Hong-Kong learned doctors will come together. Without good physicians how can we sustain lives? The modern science is superior to the old as it is more exact. I want to see some wonderful results which will outshine the past and guide the future." So much interest was shown in the proceedings of the Section of Medicine that it was decided to spread the discussions over five sessions, some thirty papers were read and debated, and the bulk of these will appear in full in the *China Medical Journal*. Irregular fighting has been going on in various parts of China for some years past, and for that reason much prominence was given in the Surgical Section to the subject of war wounds. In the Section of Obstetrics and Gynaecology there were good attendances, and the general discussions, we learn, were short and snappy. In view of the importance of the trade exhibition to delegates from districts where they are wholly out of touch with modern appliances and drugs, the Great Hall of the University was set apart for this purpose. The prudence of this decision is shown by the statement that this hall "soon became the most popular rendezvous for those not engaged in sessions and committees." Altogether the conference seems to have been a great success.

SOUTH AFRICAN MEDICAL CONGRESS

The twentieth South African Medical Congress, Pietermaritzburg, from July 6th to 11th, was opened by Sir John Dove-Wilson. The President (Dr D Campbell Watt) delivered his address on the same day. The work of the congress is divided into five sections. The members are meeting as a whole to hear the opening addresses on the subject for discussion in each section at 9 a.m., and subsequently the sections hold their separate sessions. The sectional discussions and their openers are as follows: Medicine, "Focal infection," Dr R L Gudwood; Surgery, "Treatment of carcinoma of the breast," Dr H A Moffat; Public Health, "The milk supply," Dr S J Clegg; Obstetrics and Gynaecology, "Caesarian and prevention of foetal death," Dr Lance Impey; Special Subjects Section, "The work of the laboratory in relation to the practice of medicine," Sir F Spencer Lister. Two business meetings of the congress are being held and the South African Committee of the British Medical Association meets on two of the mornings. There is a trade exhibition of drugs, instruments, and so forth, and at a public meeting in the Town Hall Dr T Shadick Higgins, M.O.H. Cape Town is giving a lecture on public health in relation to social welfare. During the week social entertainments of various kinds have been arranged, including a civic reception and a banquet. The honorary general secretary is Dr C G Kay Shup.

The next issue of the *BRITISH MEDICAL JOURNAL*, dated July 18th, will be a special commemorative number in connexion with the opening of the Association's New House by H.M. the King accompanied by Queen Mary, on Monday, July 13th, and the dedication and opening by the Archbishop of Canterbury of the Memorial Gates erected by the Association as a tribute to its members who fell in the war. Articles, letters, and information relating to other matters will for the most part be held over

NINETY-THIRD ANNUAL MEETING

of the

British Medical Association,

BATH, 1925.

BATH ABBEY

June 6th, June 20th, and July 4th, 1925

THE Annual Meeting of the British Medical Association will be held at Bath at the close of this month, under the presidency of Dr F. G. Thomson, physician to the Royal United Hospital, Bath, and consulting physician to the Royal Mineral Water Hospital. The Annual Representative Meeting will open in the Concert Hall of the Pump Room at Bath on Friday, July 17th. The statutory Annual General Meeting will be held on Tuesday afternoon, July 21st, in the Concert Hall and on the evening of the same day the new President will deliver his Address to the Association in the Palace Theatre. The twelve Sections, among which the scientific and clinical work of the meeting is being divided this year, will meet on the three following days, July 22nd, 23rd, and 24th. The list of Sections and sectional officers, together with the programme and time table and other announcements, were published in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of July 4th. On the last day of the meeting, Saturday July 25th, there will be excursions to places of interest in the neighbouring West Country, some of which are briefly described in the article printed below. Descriptive and historical articles on Bath have appeared in our issues of December 6th, 1924, and of

PLACES OF INTEREST AROUND BATH.

BY

JOHN HATTON,

DIRECTOR OF THE HOT MINERAL BATHS

Bath lies in the midst of a beautiful district, exceptionally rich in places of varied interest. The combs of Somerset, the Wiltshire Downs, and the Cotswold country of Gloucestershire, with the range of the Mendips running out into the Bristol Channel, provide an unusual variety of scenery. Stonehenge, and Wells Cathedral, the busy port and university city of Bristol, and the tiny artists' village of Castle Combe, give it houses like Longleat and Badminton, and the Cheddar Caves—all the extremes of contrast in human effort in the provision of places for worship or dwelling.

These notes cannot cover all the places selected for excursions during the meeting of the British Medical Association at Bath, but it is hoped that they will give some idea of the wealth of interest and beauty to be found in the West country.

WELLS

"The Cathedral Church of Wells," wrote Professor Freeman, "is the best example to be found in the whole world of a secular church, with its subordinate buildings. There

is no other place where you can see so many of the ancient buildings still standing, and still put to their own use."

In 909 the diocese of Wells was established by King Edward the Elder, the existing church, probably founded by King Ina of the West Saxons at the instigation of St. Aldhelm near the springs or wells which gave the place its name, served as the first cathedral. The first Norman bishop, Robert of Lewes, built a great new church, but, to an unusual degree, this massive Norman cathedral has dis-

appeared. About 1180 Bishop Reginald built or rebuilt the church and part of the present church may be said to be the work of this prelate.

In 1206 Jocelyn became bishop and it is to this great man that Wells owes its crowning glory, the West Front. Jocelyn and his brother Hugh (afterwards Bishop of Lincoln) were natives of Wells, and they loved their birthplace with an undying devotion. Hugh, who built much in Lincoln Cathedral, gave of his wealth to Wells, and Jocelyn spent all that he had upon the cathedral in which he had been canon during the episcopate of Reginald, whom he was to succeed on the bishop's stool. Old Fuller wrote, "The West Front of Wells is a masterpiece of art indeed. England affordeth not the like," and modern writers have endorsed his praise. At the top is a large niche, where was the figure of Our Lord seated in glory. Below are the twelve Apostles, St. Andrew, the patron of the church in the centre, beneath this is the resurrection course showing naked figures rising

Wells Cathedral West Front

from their graves, then come rows of saints, kings and queens, and curious biblical scenes, and a coronation of Our Lady over the main doorway. The statuary is generally agreed to be the finest collection of mediaeval statuary in England, and many of the individual figures compare favourably with the greatest masterpieces of Italy or France. In 1242, full of years and honour, the great bishop died. "God," says Fuller, "to square his great undertakings giving him a long life to his large heart."

The interest of Wells is by no means confined to the West Front. The North Porch, one of the oldest parts of the church, is a magnificent example of early work still retaining much of the Norman influence, in spite of rich undercut foliage and beautifully carved figures. The most striking feature of the interior is the curious arrangement of inverted arches built to support the great central tower. The beautiful Lady Chapel, like the side chapels, is of the Decorated period, the windows are filled with richly coloured old glass—almost all in fragments. The fourteenth century Jesse window in the choir, however, is perfect. It is a superb piece of work, probably the finest of its kind in England. One of the side chapels has recently been restored; it is the war memorial for the county of Somerset, and here is kept the beautifully illuminated Book of Remembrance containing the names of all the men of the county who gave their lives in the great war.

Before leaving the interior of the cathedral other remarkable features must be mentioned. The clock, with its little figures of knights in armour galloping wildly round at the stroke of the hour, and the unique series of carvings, full of vigour and humour, in the capitals of the piers. The Chapter House, approached by a great twisting stair, is one of the gems of English architecture. The cloisters are largely of Perpendicular work, with the library over the east wall, containing many books of extraordinary interest, including the greater part of Bishop Ken's library and many of the old book chains still hanging on the original bookcases. Near by is the mortared Bishop's Palace, entered by a drawbridge, the building itself an exquisite example of early thirteenth century domestic architecture. A great gateway, usually known as the Bishop's Lye, leads into the Market Place. On the north side of the cathedral is the Denbury, an almost perfect example of the fifteenth century house, overlooking the great Cathedral Green, which forms the ideal foreground for the West Front. Beyond, under the Choir Gate, is the Vicar's Close, a perfect street of fourteenth century houses, at the far end the little chapel of the Vicar's Choral, now used by the students of the Theological College.

GLASTONBURY ABBEY

Glastonbury Abbey, around which legend and mystery have gathered more thickly perhaps than around any other sacred spot in Britain, lies in Tennyson's

island valley of Avilion

Deep meadowed happy fair with orchard lawn,
And bowery hollows crown'd with summer sea

Here at the foot of the Great Tor St. Joseph of Annathorpe first planted in these islands the Christian faith, and the Chapel of St. Mary, more usually known as St. Joseph's Chapel, is the traditional spot upon which St. Joseph and his little band erected the original wattled church. It has been said that this was not only the first Christian church in England but the first in the world. To this spot, the legends tell us, was brought the Holy Grail. Tennyson not only records the story of the Holy Grail itself and the foundation of the Abbey, but of the famous Glastonbury thorn which still blossoms every year at Christmas tide. The most striking feature of the chapel is the beautiful Norman doorway with its richly ornamented arches adorned with sculptures.

The Abbey Church was cruciform in shape and over 550 feet in length. Still standing are three bays of the south nave aisle, the eastern piers of the central tower, part of the transept wings, one of the chapels of the northern transept, and the south wall with five pointed windows.

The discovery of the foundations of the Edgar Chapel has formed the subject of a book of unusual interest, *The Gate of Remembrance*, by Mr. F. B. Bond, F.R.I.B.A., who carried out the work of excavation. Tradition has it that the bodies of St. Joseph of Annathorpe, King Arthur, Queen Guinevere, and St. Patrick lie within the sacred ruins of this great Benedictine Abbey. It is curious that the best preserved fragment of this great group of religious

buildings should be the Abbot's Kitchen. This, like the Abbey itself, has now been acquired by the National Council, control being in the hands of a committee of trustees. The fourteenth century Abbot's kitchen is to be used as a museum for the many energetic tiles and numerous relics found in the course of the excavations.

The tower on the summit of Glastonbury Tor is all that remains of the fourteenth century Pilgrim Chapel of St. Michael. The view from the top of the Tor will find amongst the most beautiful and extensive in the county. In the High Street of the little town the fifteenth century Abbot's hostelry, now the George Hotel, will be noticed and a small building known as the Tribunal, which was originally the Abbot's justice room. Near the entrance to the Abbey precincts is the Glastonbury Museum, containing what is probably one of the finest collections of La Vieille objects in this country. The Lake Villages at Glastonbury and Merle have been systematically investigated by Dr. Arthur Bullock, F.S.A., and Mr. H. St. George Gray of Trunton Castle, and the work, which is being resumed this summer, has yielded much harvest of finds of extraordinary interest.

CHEDDAR

The limestone range of the Mendips runs from the neighbourhood of Bath out into the Bristol Channel, where outliers appear as the Steep and Flat Holme islets. The tableland itself is generally bare, but by no means uninteresting, and the slopes and numerous combs are often of great beauty. The most striking scenery is, of course, in Cheddar Gorge, the finest limestone chasm in the county. Cliffs, crowned with pinnacles, rising in some places to a height of over 400 feet, stand sheer above the winding roadway, clothed with ivy and wild flowers, and inhabited by innumerable jackdaws and other birds. It is now generally agreed that the gorge has been formed by the action of water, it was at first a great cave, or perhaps a series of caves, cut by an underground river, the roof eventually falling in, leaving the open gorge. At the foot of the gorge are the famous caves. Gough's, the larger and more impressive, contains massive stalactite formations of wonderful form. Cox's Cave is smaller, but exquisitely fairy-like in its stalactite beauty. In the village is a restored Market Cross and the Perpendicular church of St. Andrew.

BRADFORD-ON-AVON

Some nine miles from Bath, at the other end of the beautiful Limpley Stoke Valley through which run the river, the railway, and the road, is Bradford-on-Avon, a picturesque little cloth weaving town disposed in terraces of sixteenth and seventeenth century houses on the steep hillsides. Rubber factories have taken the place of the cloth mills which once produced the famous West of England broadcloth, the successors of the hand looms brought to Bradford by the Dutch weavers in the seventeenth century.

The Saxon Church of St. Lawrence, one of the most perfect and precious of Saxon relics still existing, appears to have been built about the end of the tenth century, replacing the original wooden church built by St. Adhelm in the opening years of the eleventh century. For ages this little stone church, which consists of a chancel, nave, and porch, was lost to view, being almost obscured by various excrescences which had grown about the building in the course of its misuse as a dwelling-place and workshops, and it was not until 1857, when the vicar, Canon Jones, a local antiquary looking down on the town from the hill, was struck with what would appear to be a cruciform roof, which seemed to indicate the presence of something more important than ordinary houses. The bridge is another notable feature of Bradford-on-Avon, with a Mass chapel corbelled out on one of the piers. These bridge chapels are now extremely rare in this country.

Bradford has a notable example of fourteenth century work in the great Tilt Barn, attached to the Barton Farm. This huge barn (shown in Mr. Gerard's wood engraving)

is 167½ feet long by 30 feet wide, with an Early English roof supported by huge trusses carried direct from the ground. The Hall, formerly Kingston House, was built in the seventeenth century by John Hall, a wealthy cloth merchant of the town. The handsome front of the house, rich in decoration of the Jacobean style, is set on a terrace overlooking a particularly beautiful old English garden. The British Pavilion of the Paris Exhibition of 1900 was modelled on this house as being a typical example of an English country house.

This corner of Wiltshire is distinguished for the many fine manor houses it contains. Two of exceptional beauty and interest, Great Chisfield and South Wraxall, lie in the neighbourhood of Bradford.

Farleigh Castle

This picturesque castle ruin, lately much preserved by the Office of Works, dates from the reign of Richard II, when Sir Thomas Hungerford started to build. The gatehouse remains and the chapel, and in a ruinous condition two of the minor towers. The chapel contains several Hungerford monuments and much interesting armour.

Downside Abbey

The great and growing Benedictine Abbey of Downside is on the way to becoming one of the really important modern Gothic buildings in this country. Of the Abbey Church itself much still remains to be done, but the nave which is to form the memorial of the old Downside boys who were killed in the great war, is to be consecrated on July 25th, a couple of days after the excursion to Downside in connexion with the British Medical Association. In the north transept is the shrine of Blessed Oliver Plunkett, Archbishop of Armagh, who was martyred in 1681. Attached to the community is the well known public school of Downside, which was founded at Douai about the year 1605. It was removed to this country at the time of the French Revolution, and after being carried on for twenty years at Acton Burnell, near Shrewsbury, was established at Downside in 1914.

Norton St Philip

At this little village the chief feature of interest is the half timbered George Inn, an unusually well preserved specimen of a fifteenth century hostelry. The galleries overlooking the small courtyard are still in existence, and a winding stair leads to the great room at the top of the house, formerly used as a wool market. The Duke of Monmouth made this his headquarters on the night preceding the engagement of Philip at Norton, a short time before the decisive battle of Sedgemoor.

Lacock Abbey

An interesting example of a conventual establishment, Lacock Abbey, still preserves sufficient of the Augustinian nunnery, founded in 1232, to give a very clear idea of the life of a religious house in the Middle Ages. Later work has from time to time been added, much of it extremely beautiful, and the Long Gallery and some of the other rooms contain many interesting pictures.

It was at Lacock that Fox Talbot, an ancestor of the present owner and one of the discoverers of photography, made his early experiments and succeeded in securing photographic reproductions.

Corsham Court

Corsham Court, the seat of Field Marshal Lord Methuen, is a handsome Elizabethan mansion built about 1502. The

gallery contains an exceptionally fine collection of Dutch and Flemish painting. Near the entrance to the parlour are some beautiful dishouses founded by Lady Hungerford in 1668.

Longleat

Longleat the seat of the Marquess of Bath, K.G., described by Macaulay as 'the most magnificent country house in England, is situated in Wiltshire, but a small portion of the park lies in Somerset. The building was started in 1567 by Sir John Thynne, an ancestor of the present owner, and the design is in the characteristic sixteenth century style in which Italian influence is prominent. The beautiful park of 2,000 acres contains a large herd of deer. The lake is fed by the long leat from which the place gets its name. The finest viewpoint is justly known as Heaven's Gate. When the saintly Bishop Ken was deprived of his see he was welcomed to Longleat, and there he wrote those well known morning and evening hymns: 'Awake my soul, and with the sun, and glory to Thee, my God, this night. The Bishop was buried at Frome, where his grave may be seen at the east end of the beautiful St John's Church.

Tithe Barn interior Bradford on Avon (From a wood engraving by Horace Gerrard)

Bristol

Eleven miles from Bath, where the Avon is still navigable from the sea by outgoing steamers, is the great port and commercial city of Bristol. The city has a population of 350,000 and an unusual variety of industries, including world famous tobacco and chocolate factories and aeroplane works. The early history of Bristol and its strongly fortified castle is full of interest, but there is only space in these notes to refer to some of the most important features of the city as it is to-day.

As befits a city whence John and Sebastian Cabot sailed to discover the American continent, Bristol is primarily a port, and in the midst of its busy streets, and almost under the cathedral walls, there is still a suggestion of the Merchant Venturers of other days in the sight of a tall ship lying alongside the modern steamers at the city quays.

But the size of modern ships has rendered vast new docks nearer the mouth of the river necessary, and the corporation has spent over seven million pounds in the establishment of Avonmouth, where the largest of the docks has an entrance lock of 875 feet, and a depth of water over the sill of 35 to 45 feet in ordinary tides. Vast cold stores, grain docks, grain elevators, and warehouses and discharging stations enable the ever-increasing trade in grain, meat, timber, and oil to be dealt with expeditiously. The fruit traffic and the passenger traffic, especially to the West Indies, New Zealand, and Canada, are extending every year.

Bristol Cathedral contains much of interest, its most striking feature perhaps being the fine Norman doorway. It was originally the church of an abbey of Augustinian monks. Founded in 1142, there appears to be little doubt that an earlier church stood on the site. The vestibule to the Chapter House is very beautiful, and the graceful Early English Lady Chapel is of particular interest. It has some good examples of Early English, Decorated, and Perpendicular styles of architecture, and underwent extensive restoration in 1860-61.

Bristol also possesses in St Mary Redcliffe Church what is generally admitted to be the finest parish church in England. This exquisite building—

‘This mystery of a human hand,
The pride of Limestone and the Western land’—

with its graceful spire, claimed by many to be the finest example of Perpendicular architecture in England, was largely built in the fourteenth and fifteenth centuries by the Cringes, two of the most famous of Bristol's Merchant Venturers. It was in the monument room in the tower that the boy poet Chatterton claimed to have discovered the Rowley manuscripts.

Bristol owes much to the munificence of the Wills family, and amongst the monuments of their generosity is a very fine Municipal Art Gallery. Isolated with the gallery is an unusually complete museum, which, by the way, is about to be further extended through the same generous hand. The geological department, the Drane Family Smyth botanical room, the Greville-Smith insect room, and the section illustrating the history of the city, containing much Bristol elf and Nilsen glass, are all of exceptional interest.

Bristol University is rapidly making history. It was only erected by a charter of King Edward VII sixteen years ago, and it already possesses the finest buildings of any modern university in Britain. Last month His Majesty the King opened the magnificent new block, given, at a cost of over half a million pounds, by Sir George Wills and his late brother, Mr H. H. Wills. (A description of the building and the opening ceremony appeared in the *BRITISH MEDICAL JOURNAL* of June 13th, 1925, p. 1098.) The most striking feature of this block is the University Tower, a truly magnificent piece of modern Gothic architecture. Rising to a height of over 200 feet, it is visible from many parts of the city. The belfry contains a great 10-ton bell, which has been christened Great George. The entrance hall beneath the tower contains some fine fan vaulting and a flight of stone steps leading to the Great Hall, of which the hammer-beam roof of English oak is a notable feature. The Faculty of Arts is housed in this building, the buildings erected for the Faculties of Science and Medicine are behind, and the Faculty of Engineering is housed at the Merchant Venturers' College. A new building on St Michael's Hill is now being erected for the Department of Physics. Next at hand are the Victoria Rooms, now the clubrooms and hall for the University of Bristol Union. Research work in fruit-growing is carried on at the University orchards at Long Ashton. The well known public school, Clifton College, is near by.

Bristol has many other features of interest. The Clifton Downs, on which stands the Cabot Tower, whence a superb view is obtained of the city and surrounding country, the magnificent Avon Gorge, spanned by the Suspension Bridge, a well stocked Zoological Garden, the Royal West of England Academy, at which educational work is carried on and an important annual exhibition held, and the Royal Colonial Institute, an active centre for visitors from the distant countries of the Empire.

One of the most notable of the old buildings of Bristol is the Red Lodge, a mansion built by the wealthy merchant Sir John Young in 1590. The Red Lodge has a handsome staircase and a magnificent carved chamber on the first floor. The whole building, full of objects of extreme interest, is in the care of the Bristol Savages, a club of artists and others interested in art generally.

Bristol possesses two large well equipped hospitals—the Royal Infirmary and the General Hospital—as well as a number of special hospitals.

THE STATE OF THE PUBLIC HEALTH.

SIR GEORGE NEWMAN'S REPORT FOR 1924
ENGLAND AND WALES

[First Notice]

THE annual report of the Chief Medical Officer of the Ministry of Health for 1924 has been issued. It deals with England and Wales, and the statistics it contains are founded on the returns published by the Registrar General relating to births, deaths, and infectious diseases, and on the various data and records in respect of vital data under the National Health Insurance Acts, supplemented by annual and special reports of medical officers of health, and from the results of investigations by medical officers of the Ministry and other departments interested in the physical, industrial, and social welfare of the people.

The report contains twelve chapters, and follows the general lines of its five predecessors, but in one chapter the administration of the Insurance Medical Service has been dealt with more fully than usual. To this we hope to return later. We may note at once that Sir George Newman again points out that the work is done quietly, without ostentation, with scant public recognition, often without thanks or reward other than the consciousness of work well done. The types of the few become conspicuous, the great volume of valuable work done by the vast majority passes unnoticed.

Births and Deaths

In 1924 there were 28,198 fewer births and 28,450 more deaths than in 1923. The birth rate was 18.8 per 1,000 of population, a decline of 0.9 on the previous year and of 6.7 as compared with 1920. The death rate was 12.2 per 1,000 persons living, which is 0.6 higher than in the previous year but among the lowest in the history of the country. The decline in the death rate has been accompanied by a steady reduction in the birth rate from an average of 21.8 per 1,000 persons living in the decennium 1911-20 to 18.8 in the year 1924. With the exception of the war years the birth rate in 1924 was the lowest yet recorded. Sir George Newman considers it highly probable that the crude mortality rate is now at or near its lowest point and will hereafter increase, owing to the change in the distribution of age groups of the population. A declining birth rate, he points out, implies an increase of the average age of population, not necessarily any strengthening of the forces of mortality.

The diseases to which the most noteworthy increases in deaths were attributed are set out in the following table.

	Per 1,000 deaths
Bronchitis, pneumonia, and other respiratory diseases	174
Diseases of heart and circulation	168
Cancer and malignant disease	106
Diseases of the nervous system	100
All forms of tuberculosis	87

Infant Mortality

Ignoring for the present the effect of illegitimacy, the infant mortality shows an increase over 1923 at all periods of the first year of life. It is pointed out that a high infant mortality rate implies (a) the loss of many infants, (b) the maiming of many surviving children, for conditions which kill some injure others, (c) a high death rate in the next four years of child life, and (d) the existence of unhealthy conditions in the mothers or in the home life of the people. The infant mortality was 75 per 1,000 births. Calculated on the average infant mortality of 1901-10, there was in 1924 a saving of 39,000 infant lives. It implies a better physical condition in children from 1 to 5 years of age, and a more enlightened understanding of personal and public hygiene. What is described as the "closely related mortality among women in childbirth" still remains high, and has shown little or no improvement since 1894. The number of women who died in childbirth was 2,703, and 144 died from conditions associated with it. Of the 2,847 as many as 1,018 died from puerperal fever—"a preventable condition."

¹ *The State of the Public Health*. Annual Report of the Chief Medical Officer of the Ministry of Health for the Year 1924. H.M. Stationery Office (Med. Soc. pp. 256 3 6d net).

In commenting on the statistics Sir George Newman points out that the relative slightness of the decline of mortality in the first month of life is consistent with the belief that neglect of ante-natal hygiene has had all consequences, but that the fact that some improvement, even in the first month of life, has been achieved is of hopeful augury. The evidence, he states, appears to show that whether or not some biological change is taking place in the reduction of virulence of certain maladies and infectious-affecting children under 1 year of age, the predominant factor in the recent improved health of infancy is to be found in better mothering, proper food, and improved domestic conditions immediately concerned with child welfare. He warns us, however, against false confidence. International comparisons and other observations show that the problem is very complicated, and it is vain to argue that any one hygienic measure is sufficient wholly to account for the movement of the rate of mortality. Sir George Newman writes:

'When an historian says that the average citizen of 1925 is more civilized than the average citizen of 1725 he is making a general statement dependent upon a multitude of interrelated particulars and nobody is foolish enough to attribute the change to any one difference to say that man is more civilized now because such and such particular changes have come about. Unfortunately in medical history this particularism is ever and again repeated. We read that in such or such a town infant mortality began to decline when an infant welfare centre was established; therefore the welfare centre caused the decline. We have not long to wait before another particularist publishes the statistics of another town where infant mortality declined without the establishment of a welfare centre, therefore welfare centres are valueless. Both conclusions are worthless in logic yet both are triumphantly paraded by the sectaries to which they appeal. The lessons which other students of social evolution learned long ago—the lesson of the multiplicity of causation, is one that cannot be too often or too strongly impressed upon the student of communal hygiene. The history of infant mortality affords many instances of its truth.'

Small-pox

The second section of the report deals with general epidemiology, and special attention is directed to the serious increase in the group of epidemic diseases of the central nervous system—poliomyelitis, poliomyelitis, encephalitis lethargica—to the recrudescence of influenza in the early part of the year, and to the continued increase in the prevalence of small-pox. The net total number of cases of small-pox notified in England (there were none in Wales) during 1924 (after revision of diagnosis) was 3,797, as compared with 2,504 in 1923. Eight cases were notified and verified in port sanitary districts. The number of deaths was 8, including one port case. A table is given showing that from 1911 to 1917 the number of cases diminished, but that from that year onward the number has increased: there were 7 in 1917, and 3,797 in 1924. In the first four months of 1925 the number (as yet unreviewed) was 2,214, with 3 deaths. The regional distribution was irregular. In London there were only 4 cases, in Derbyshire there were 1,351, in the North Riding of Yorkshire 539, in Nottinghamshire 536, in Northumberland 401, in Cumberland 186. Altogether, excluding the port sanitary districts, small-pox occurred in 119 out of a total of 169 sanitary ports in England. The general character of the disease since it began to increase in England has been mild and the mortality low. The occurrence of small-pox of a mild type has been a frequent feature in the history of the disease. Sir George Newman examines the suggestion that the mild type should be distinguished from true small-pox and given a separate name. He does not accept this view, and observes that the sound principle is "that notifiable specific disease should be notified as such, whether the attack be severe or mild," and whether it be scarlet fever, enteric fever, diphtheria, encephalitis lethargica, or small-pox. "or the control of small-pox the chief need is eradication, and, he says, "successful vaccination and re-vaccination constitute the only efficient protection against small-pox whether of the mild or severe form," he states further "that though early diagnosis, prompt isolation of small-pox patients in suitable hospitals, effective disinfection, supervision of 'contacts,' and other such public health methods are invaluable they are no substitute for vaccination."

(To be continued.)

Scotland.

EXTENSION OF ANTE-NATAL CLINICS IN EDINBURGH

At a meeting of the directors of the Edinburgh Royal Maternity and Simpson Memorial Hospital on June 26th it was intimated that the great popularity of the welfare clinics for mothers and children organized by the hospital had made it necessary for the directors to require additional accommodation. The pressure on the outpatient department had in recent months been very great and the clinics, which were at first held twice a week, were now open on five days a week. The total number of visits to the clinic had increased from 2,444 in 1920 to 6,073 in 1924. An adjoining house had been bought and was in process of being adapted for the purpose of the clinics, and when this was complete it was hoped that the department would be worthy adjunct to the Royal Maternity Hospital, which had been the pioneer institution in establishing clinics for the expectant mother.

ROYAL (DIET) VETERINARY COLLEGE, EDINBURGH

Sir Robert Greig, chairman of the Board of Agriculture for Scotland, distributed on July 1st the prizes at the Royal (Diet) Veterinary College, Edinburgh. Professor Hudson Beve, chairman of the board of governors, who presided, said that the college had been for some years in occupation of its present premises, but until recently, owing to lack of money, the fittings had been deficient. All the laboratories, classrooms, and lecture rooms were, however, now being fitted. The board of governors was making arrangements for an official opening in October, and he had no doubt that next session the amenities of the college would be vastly improved. It was hoped that it might in future rely upon the generosity of some of the wealthier citizens of Scotland to endow the college. Research was urgently needed in many directions—for example, in connexion with animal breeding and diseases and for improvement of the livestock. Sir Robert Greig, in his address to the students, said that if they expected to make a fortune out of their profession he feared they would be disappointed, but if they wanted a profession in which they could feel sure that they could put a great deal into their life, then they had been fortunate in their choice. More and more their profession was linking up with the medical profession, more and more preventive medicine involved the veterinary profession, and more and more did comparative pathology and physiology throw light upon human disease. In the last few years several institutions devoted to the study of the physiology and nutrition of animals had arisen in Scotland, and there were now more appointments for first-class investigators than there were first-class investigators to fill them. The public services of the veterinary profession became more extensive every year, and a further important extension would be brought about by the Milk and Dairies Acts which came into operation on September 1st next. He looked forward to still greater development of the status and usefulness of the veterinary profession.

ROYAL SANITARY INSTITUTE CONGRESS

The thirty-sixth congress and health exhibition at the Royal Sanitary Institute, which is to be held at Edinburgh from July 20th to 25th under the presidency of Sir John Gilmour, the Secretary for Scotland, will be attended by more than 800 delegates from public health bodies, departments of home and Dominion Governments, and representatives from foreign countries, including the United States, France, China, and Japan. The congress is divided into five sections—namely, sanitary science, under the presidency of Sir George Newman, engineering and architecture, maternity and child welfare, personal and domestic hygiene and industrial hygiene, under the presidency of Dr. W. E. Elliot, Parliamentary Under-Secretary of Health for Scotland. During the congress various conferences have been arranged for representatives of sanitary authorities, medical officers of health, engineers and surveyors, veterinary inspectors, and health visitors. The Lord Provost of Edinburgh will hold a reception for the

members and delegates on July 20th, and lectures to the congress will be delivered by Sir Leslie Mackenzie and Dr Charles Porter. In connexion with the congress a health exhibition will be held in the Watcley Market.

SCOTTISH OPTICIANS AND MEDICAL BENEFIT

At a meeting of the 1st of Scotland Branch of the British Optical Association on June 23rd the question of optical benefits under national health insurance was discussed. Mr Archibald Young presided, and a resolution was unanimously passed that the association should protest against the recommendations issued by the Insurance Department of the Ministry of Health in taking away the right of insured persons to consult opticians when needing glasses, and requiring instead the production of a medical certificate before a claim for optical treatment could be accepted by an approved society. In support of this resolution it was urged that the recommendations of the Insurance Department of the Ministry of Health were absurd, because of the inability of the general medical practitioner to estimate the refraction of the eye, and that they were extravagant because of the expense to approved societies if, as was suggested, insured persons from all over Scotland should be required to travel to one or other of the few centres where properly qualified ophthalmic medical practitioners or hospitals were to be found.

Ireland.

ROYAL MEDICAL BENEFICENT FUND SOCIETY OF IRELAND

In submitting the eighty-third annual report of the Royal Medical Benevolent Fund Society of Ireland the central committee states the number of grants awarded during the year was 86, an increase of 3 as compared with the preceding year. Of these 5 were made to medical men, 8 to orphans, and 73 to widows. The amount disbursed in grants was £1,755, as compared with £1,540 in 1923-24. The average amount of the grants has thus increased from £18 10s 7d in the former year to £20 8s in that now under review. In presenting the audited balance sheets of the general fund and of the Osborne fund the committee once again wishes to express its thanks to the honorary secretaries of the branches for their work, and to the individual subscribers for their support. The income of the general fund from all sources amounted to £2,097 1s 6d. In this is included the sum of £422 15s 10d, the amount of income tax refunded for two years, the receipts under this heading during the current year will be only about half of that amount. Dividends and interest yielded an increase of income of £48 19s 2d. Subscriptions paid through branches, including those of the Dublin area, show an increase of £21 9s 6d, while those paid through the central treasurer have increased by £20 5s. The British Medical Association is thanked for collecting £26 13s. Donations amounted to £21 10s, being a life-membership payment of £10 10s by the President of the Royal College of Surgeons, Mr R C B Maunsell, and £11, the "Thankoffering of a Widow" who at a time of dire need received a special grant from the fund. The Irish Medical Association sent £20 and the Dublin Clinical Club £5 5s. No legacies were received during the year, nor was any addition made to the invested capital of the fund. At the beginning of the year the Osborne fund stood indebted to the general fund to the amount of £220 18s 5d. On June 18th, 1924, the central committee, having reviewed the position, resolved to suspend charges on the Osborne fund until such time as it showed a credit balance. In accordance with this resolution all grants have been charged to the general fund, and at April 30th, 1925, the indebtedness of the Osborne fund had been reduced to £109 12s 8d. Looking to the future, there are some factors which cause the central committee anxiety. There has been a fall in the capital value of railway stocks, and the matter has been submitted to the trustees for consideration and such action as they deem fit. The country is passing through a period of financial stress, and in common with all classes of the community medical men have suffered, and that the subscription

list has shown some increase is felt to be a matter for congratulation. Those who subscribe do so generously and merit thanks, but the committee asks for the support of the many who have not hitherto helped the fund, to enable it to bring relief to those connected with the profession in Ireland who come to it in their time of need. Only by widening the field of support can the fund be maintained on a sound financial basis.

England and Wales.

ROYAL NATIONAL SANATORIUM, BOURNEMOUTH

VISCOUNT HAMBLETON, who has been elected president of the Royal National Sanatorium, Bournemouth, of which he had for many years been treasurer, presided over the annual meeting, when it was mentioned that the institution had been in existence for seventy years, and that Bournemouth was selected as the place at which it should be established after very full inquiries. The annual report submitted by Dr F G Penrose stated that 97 patients were in the institution on January 1st, 1924, that 350 (164 men and 186 women) were admitted during the year, that 342 (158 men and 184 women) had been discharged during the year, and that there had been 16 deaths. The daily average number of patients under treatment for the year was 94. A considerable number of patients when discharged were fit to resume their occupations with a reasonable expectation of permanent benefit from the treatment received. The financial position was satisfactory—the total ordinary income amounting to £11,555, and the ordinary expenditure to £10,163. A legacy had been bequeathed by Miss Julia Thomas to cover the expenses of the free treatment of poor patients who for a year previously had usually resided in the County of London. At the request of the Ministry of Health the charge for the treatment and maintenance of patients sent by local authorities had been reduced from £2 5s 6d to £2 3s a week, and this would thus reduce proportionately the annual income received from this source. A vote of thanks to the committee was passed on the motion of Mr F G Lefroy, seconded by Dr Hila Greaves, and the chairman then proposed a vote of thanks to the medical, surgical, and dental staffs, which was carried by acclamation. After a vote of thanks had been passed to the chairman those present made an inspection of the institution.

THE MIDDLESSEX HOSPITAL

Mr T R Feens of Hull has presented £20,000 to the medical school of the Middlesex Hospital to provide an institute of otology, with special facilities for research in connexion with the ear, nose, and throat. It is proposed at first to install the institute on the top floor of the reconstructed buildings in Cleveland Street, where patients are to be housed during the rebuilding of the hospital. A laboratory, museum, and library will be established, and facilities will be given for post-graduate and otological study and research. It is possible that studentships will be endowed subsequently if further financial support is obtained. The institute will enable post-graduate students from America and the Dominions to complete their studies in London, and English students will no longer find it necessary to visit the Continent for such work.

TRAINING OF HEALTH VISITORS

We referred on February 21st, 1925 (p. 384), to a memorandum (101/M C W) issued by the Ministry of Health detailing the conditions on which grants for the training of health visitors will be given, and stating that, as a condition of the payment of grant, students who take either of the courses of training specified in the memorandum will be required to enter for an examination to be conducted by a central examining body approved by the Minister for this purpose. The Minister has now approved the Royal Sanitary Institute as the central examining body to conduct the examinations for health visitors in accordance with the conditions prescribed in the memorandum, and to issue health visitor's

then functional position, and at the request of the Commission I give them my opinion (which they adopted) as to the best way of carrying it out.

I had no intention of occupying your columns by a discussion on the merits of this question. The college has always been perfectly ready to discuss them. They were fully before the meeting of the court of governors of the college last month, and not a voice was raised in favour of separation. My only object was to point out certain apparent misconceptions as to the present position of the question—I am, etc.,

Capetulo Penmaenmawr, July 6th

ISAIAH OWEN

REVERSE PERISTALSIS

SIR,—Cases like that described by Dr R E Lord (BRITISH MEDICAL JOURNAL, July 4th, p 13) are still discredited by many doctors, and even by many Roentgen-ray specialists. What the latter describe as "antiperistalsis" is something very much less in degree than the vomiting of formed faeces which have been passed upwards from the colon—probably from the descending colon—by reversed peristalsis, through the ileo-caecal valve (or what represents it) and the pylorus. I have taken considerable interest in the subject, especially since 1904, when I wrote a paper entitled "Faecal vomiting and reversed peristalsis in a functional nervous case." One of my conclusions then was

"Vomiting of formed faeces in the absence of malinger and gastro-colic fistula, practically only occurs in functional nervous cases. This may partly be accounted for by remembering that antiperistalsis, if it occurs at all, is likely to be more foreboding when the muscular walls of the gut have not been previously weakened by overdistension or gross organic disease."

I now believe that vomiting of formed faeces does not occur in cases of gastro-colic fistula. Malinger (that is, the swallowing of formed faeces and then vomiting them up again) can hardly ever be seriously entertained as an explanation. It appears also that vomiting of formed faeces (actual scybala) never occurs in any case of gross organic intestinal disease, but I would not now like to say that the presence of nervous disease (whether functional or not) is necessary for its occurrence. Surely, all cases of severe constipation in which relief, with vomiting, is obtained by the use of enemata suggest that antiperistalsis is called into play—I am, etc.,

F PARKES WEBER

London, W 1, July 4th.

RAW PANCREAS BY THE MOUTH IN THE TREATMENT OF DIABETES

SIR,—May I add the following experiment to that published in your issue of June 13th, to show that fresh raw pancreas by the mouth is useless in the treatment of any type of diabetes? Drs Harrison, Graham, and myself proved that raw pancreas is no substitute for insulin, a point which our opponents admit. But then claim that it is beneficial in non-insulin cases is apparently still maintained. The following two cases showed no benefit at all from raw pancreas by the mouth.

Case A, a woman aged 48, is a mild obese diabetic. Case B a woman aged 58, is moderately severe and there is retinitis. Both were suffering from marked glycosuria before admission to King's College Hospital, but a diet of 45 grams carbohydrate, 70 grams protein, and 135 grams fat in Case A and 35 grams carbohydrate, 50 grams protein, and 105 grams fat in Case B, rendered them aglycosuric with normal blood sugar after two weeks in hospital. A diabetic condition was then reproduced by the gradual addition of bread to the above fixed diets ultimately 9 oz a day to Case A and 6 oz to Case B. The total glucose excreted in the urine was estimated daily, and when constant 1 oz of fresh raw pancreas was added to the daily diet in the form of a sandwich which they disliked very much. This pancreas was supplied by the courtesy of the British Drug Houses in the same fresh frozen condition which they find yields the maximum of insulin and was eaten within half an hour of removal from the ice chest. All the conditions of the experiment were kept constant, and the figures are recorded in the following table. One ounce of pancreas was given for a week—these days are indicated by an asterisk. Only two days before and after the administration of pancreas are recorded.

Days	Grams of Glucose Excreted		Days	Grams of Glucose Excreted	
	Case A	Case B		Case A	Case B
1	15.2	70.2	6*	16.75	137.14
2	14.9	137.0	7*	23.4	123.88
3*	22.54	142.88	8*	17.5	130.03
4*	13.31	135.39	9	12.49	119.81
5*	17.75	126.2	10	14.82	133.48

1 oz pancreas given by the mouth

The amount of glucose excreted in both cases is very constant considering that over 100 grams is being lost in one case and the difficulty of collecting complete samples of urine in a busy general ward. The first figure in Case B is much lower than the rest because her preliminary stabilization had to be hurried on account of the retinitis, and because she threatened to leave hospital to attend a wedding. An extra 3 oz of bread had been added to her diet only three days previously, and the full effect of this was not manifested until the second figure recorded.

It seems clear from the figures that the administration of raw pancreas had no effect on the amount of glucose excreted, and did not enable these two diabetics either to store or burn more sugar. I find it difficult to avoid the conclusion that the beneficial effect of raw pancreas which has been recorded in your columns was obtained by concurrent dietetic treatment, and not by the virtue of pancreas by the mouth—I am, etc.,

R D LAWRENCE

King's College Hospital London July 3rd

BRITISH MEDICAL WOMEN FOR INDIA

SIR,—My experience may be of interest to "Medical Woman" who asked in the BRITISH MEDICAL JOURNAL of June 27th (p 1195) for information about work in India. I worked there for several years, chiefly in the mission field. I returned to England a few years ago, for private reasons, unconnected with health. I was always well while I was abroad, and stood a very hot climate much better than most Europeans (for example, I could walk six miles when the thermometer was 115° in the shade). I learnt two Indian languages well, and a little of others. I learnt languages quickly. I passed the examinations for those two in half the usual time, getting over 90 per cent marks. Recently I have taken up another language, quite different from any I have learnt before, and in a month have learnt enough to read the New Testament fairly easily.

As I am now entirely free, have no dependants, and wish to go somewhere where workers are needed, I have lately applied to several societies to be sent abroad again, anywhere. But so far I have not found any to do this. The reason given is that my age is over 35, and they have so many applicants, while funds are so low that they must stick to age limits. I have good testimonials, medical and otherwise. I am told that Government appointments in India are usually given to Indians. In South Africa a three years' preliminary residence is essential.

Private practice could probably be obtained in some parts by anyone who had capital enough to wait for it, and could learn languages and understand the people. I also should be grateful if those who talk so glibly about the East absorbing surplus medical women would explain clearly how and where—I am, etc.,

July 5th

ANOTHER MEDICAL WOMAN

SIR,—For nine months I have tried to get any sort of medical work abroad, in India or any colony, with the most complete success. I have an honours arts degree and the Diploma in Tropical Medicine, the latter the Colonial Office considers of sufficient value to warrant its paying the fees for the course for many of its men applicants.

An application to the Colonial Office brought a lugubrious reply, kindly letting me know the worst at once. While

¹ Brain London 1904 vol xxvii pp 170 178

² Aided by a grant from the Medical Research Council.

my application would be "carefully considered," there were very few posts open to women. An application to the Duffield Fund had no result whatever.

There remain the missionary societies and private practice. The former can be possible for relatively few people. In the first place, several societies put applicants through a theological mill which grinds exceedingly small. Secondly, there is a barrade of intimate religious questions which, to anyone with a quite ordinary amount of reserve, are very objectionable to answer, to a committee of strangers especially. Thirdly, while the problem of keeping body and soul is closely united as possible on £150 a year in a tropical country has quite a lot of intrinsic interest, considered as a puzzle of personal application it is unlikely to have much attraction for the ordinary mind.

In India (the native States excluded, where the native product is preferred) private practice presents the most hopeful prospect, but this is by no means so shining as some, usually non-medical, enthusiasts would have one believe. The intending practitioner must have sufficient capital to live on for a year, she will have to compete with not only an ever-increasing number of native women doctors, but with the many doctors, with the bazaar medicine men, who can tell by feeling a pulse whether it is the tibia or fibula which is fractured—but who have the confidence of the people, and with the missionaries who do private work. She will have to learn a new language or languages, to learn the quite intricate ropes of a strange country, to try to understand a strange and by no means simple type of mentality, and she must be able to carry on in the heat month after month. If one has not friends there, putting up one's plate in an Indian town is a somewhat grim vision.

The melancholy truth is that there are too many doctors, and far too many women doctors. This statement of a very obvious fact is naturally not popular with medical school authorities, but the students know all about it when they qualify and think that their troubles are over.

If I am wrong, perhaps these apparently mythical providers of lucrative or any other kind of jobs will take on flesh and blood, come out of the impenetrable darkness in which they are shrouded, and come down to brass tacks. Most important of all, perhaps they will give us their postal address.

The higher caste, too, who turn up periodically and is good enough to inform us, *ex cathedra*, that the reason why medical women cannot get work abroad is that they are unwilling to undertake the responsibility which the pioneers (*requiescant in pace*) undertook—perhaps she will tell us whether she ever had a job in the tropics, if so, how she managed to get it, if not, the adoption of a less lofty tone on her part would be more suitable.—I am, etc.,

A WOMAN G.P.

BRITISH SOCIAL HYGIENE COUNCIL

SIR,—The real importance of the decision of the National Council for Combating Venereal Diseases to change its name to that of the British Social Hygiene Council lies in the intention to embark on a wider constructive and preventive effort, which will embrace not only venereal disease but all disease and inefficiency, in so far, that is, as voluntary effort in co-operation with Government action can render effective service in such a campaign.

The undertaking of this forward movement indicates some important facts. It illustrates the tardy but growing recognition by voluntary societies and by Government departments of the essential unity which underlies bodily, mental, and moral health. Further, it shows that we are beginning to realize that before we can establish a vigorous and healthy or a happy population in this or in any other country, we must individually and collectively appreciate and understand the intimate association which exists, not only between health and conduct, but also between conduct and health.

In the increasing complexity of our modern civilization, national well-being depends more and more on the conduct of the individual citizen. This fact stands out very clearly in the case of venereal disease in its relation to sexual

promiscuity, hence the urgent necessity for building up a "national health conscience," a real appreciation of the fact that it is "wrong to be ill" if the illness be preventable, just as it is "wrong to be ignorant" now that education is available for every citizen. It is even more important still to arouse in the minds of our people a "racial conscience," a pride of race which will enable an enlightened public opinion to focus attention on the great responsibility which rests on every individual to place the interests and the welfare of the young, and of the next and succeeding generations, in the very forefront of every progressive movement.

These and other considerations surely provide an abundant justification for the decision of the Council to aid to the utmost extent the movement for providing for the adolescent population sound instruction and wise advice in the principles which underlie the right living of the sex life, in short, in sex hygiene in its wider physical, mental, and moral aspects.

The outstanding feature of our present-day social life is the fact that parents are not giving such instruction to their children on any adequate scale. The churches and other religious bodies have so far failed to fill up the gap. Our scheme of national education has not devoted that attention to instruction in personal, sexual, and social hygiene, or to citizenship in the wider sense, which the vital importance to the nation of the subject demands. The causes of this educational failure are complex, but the consequences are apparent in the youthful life in our cities. But if we are to hold our own among the nations of the world this gap must be filled. Instruction and guidance in health and right living in every department of life, individual and communal must be given to the young, and it must be given to boys and girls at the right time and at an age when it can be of real use in building up character. The difficulty is that at present teachers are not available. It will be necessary to start with the training colleges and build up a body of teachers fitted, both by natural inclination and by special training, to instruct and advise the youthful population in sex hygiene, and to help the parents in teaching their children.

The great work which the British Social Hygiene Council under its old name has already done in opening up the field, and in building up a sounder public opinion in the matter of the sex relationships, will be of the greatest help in bringing about further progress.—I am, etc.,

C. J. BARN, CMG, FRCS.

Vice-Chairman, Medical Consultative Council, Ministry of Health.
Member of the Industrial Fatigue Research Board.
Vice-President, Leicester Royal Infirmary.

July 4th

DISEASES DUE TO FASHION IN CLOTHING

SIR,—I do not think that Dr. Parkes Weber and I differ very profoundly as to either of the two diseases under discussion. The erythema I was referring to was exactly the same as that exhibited by his cases. I am familiar with the reticulated mottling due to sitting before the fire seen so often in delicate persons and old people. What I am not sure about is that there are not other factors than mere dry cold determining the incidence of the erythema described by Dr. Parkes Weber. I question whether dry cold alone produces chilblains, and, as I stated, I believe this condition to be practically chilblain modified, in that the area affected is often very extensive, not the usual situation associated with chilblains, and not so much accompanied by itching. Chilblains are more common in some types of circulation, are most commonly seen on the feet, the hands, and the face, especially on the nose and ears, and I think that dampness as well as cold and frost has something to do with their production. Frequent changing of socks, so avoiding the slight dampness that results from the socks when worn any length of time, is a preventive. The dampness results from want of free evaporation of the moisture from the skin, such evaporation being prevented by the leather of the boot. Boots that are lined, and some kinds of leather, are better in this respect than others, because of being more pervious. The worst kind of leather for boots in cold weather is

patent leather Rubber overshoes have this disadvantage, but it is made up for by the fact that they keep moisture from getting into the foot, and they also keep the cold outside moisture or slush further away from the foot. Hands that are not put much in water are also more free from chilblains. When the nose and ears are affected it is often after being exposed to frosty, foggy weather, or sleet and snow. Exposure to heat before the fire after the chillings above referred to undoubtedly aggravates the condition. I believe the same conditions apply to the extremities of the legs.

The cases I have seen have been in girls wearing artificial silk stockings. Perhaps some chemist or physicist can say whether artificial silk is more likely to absorb and retain moisture as in frosty and foggy weather than natural silk or the fibre of wool. Wool certainly does not cling so closely to the skin, and the stockings are thicker than silk. But whether silk may actually retain moisture in damp, frosty, or foggy weather might be a point of interest. Whilst, therefore, cold is the initial cause, as Dr Weber states, dampness and exposure to a fire aggravate it.

As regards chlorosis, I believe Dr Weber is right in showing the important part taken by the tight corset in its causation, but there are some considerations that make it difficult to believe that it is the only cause.

Chlorosis has been known from the earliest times. I believe it was known to Hippocrates. It was described under its present name by Varicoll in 1620, Sydenham has a chapter on it about 1660-70. It was known to Willis, Boerhaave, and Cullen (seventeenth and eighteenth centuries), and was common in the nineteenth century. I am not familiar with the changes that have taken place in ladies' dress fashions, but is it a fact that ladies have worn tight corsets during all those periods? This is not the first time that corsets have been blamed for it.

I agree with Dr Prakes Weber that rest in bed for a short time and administration of iron was the best line of treatment, but as he has seen cases recover under rest and iron in a basement, so I have often seen cases recover under no other form of treatment than rest, plenty of fresh air, and mild laxatives, iron not being necessary if rest was combined with other hygienic conditions. The reason that rest was necessary—at least at the beginning of treatment—was that the oxygen-carrying haemoglobin in the blood was often so far reduced that it was too great a strain on the heart, digestion, and other parts of the system for the girl to indulge in any sort of exertion, especially when she was wearing tight corsets.

While the tight corset has been largely discarded in recent years, there has probably been a greater change in the life and habits of civilized girls during the last twenty years than there had been during the previous twenty centuries. As I stated in my previous letter, the cult of fresh air, along with free movements and exercises in the open air, have been welcome changes in the habits of girls. The tight corset, therefore, important as it was as a causative agent, was, I believe, only one cause amongst several—I am, etc.,

Leith, June 28th

WILLIAM ELDER

ULTRA-VIOLET LIGHT

SIR,—Mr A. Blakston, in your issue of June 20th (p. 1153), states that the cost of a tungsten arc lamp is £300 per 1,000 hours worked. A tungsten arc lamp of the "Dr. Percy Hall" type has been in use in a municipal clinic of this city for the past fifteen months. Careful records of the cost have been kept, and they work out as under:

	£	s	d
Electricity—1 unit per hour at 5d per unit for 1,000 hours	20	16	8
Tungsten electrodes cost 1s 0½d per hour for 1,000 hours	52	1	8
Total	£72	18	4

—I am, etc.,

W ALLEN DALEY M.D.

Health Department Guildhall,
Hull June 23rd.

MEDICAL MEN ON THE PIPE ROLLS

SIR,—I think that both your readers and Mr R. R. James (June 27th, p. 1189) will be interested to learn that the earliest Pipe Roll entry referring to a "Medicus" is to be found in the Roll for Notts and Derby of 1129-1130 (31 Henry I). It is as follows:

Gislebertus de Plesni medicus reddit compotum de 45 marcis argenti pro terra et filia Johannis de Monte Calvino. In thesauro £4 et debet £26.

This means that Gilbert paid the King £30 for a licence to marry the heiress of Monto Calvino. He paid £4 on account in 1129-1130, leaving a balance of £26 to be paid during the next financial year. To judge by the amount of the "fine" Johann must have been a wealthy bride—I am, etc.,

Clifton Bristol July 2nd

R S S STATHAM, M.D.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

THE House of Commons has this week given a second reading to the Unemployment Insurance Bill and has debated the trade outlook and the difficulties of the coal-mining industry. Speaking in the House of Lords, Lord Birkenhead, Secretary for India, said that the position of the civil services in India would be one of the subjects to be investigated by a Royal Commission on Indian Government. Until public servants in India could feel that unfair or capricious criticism would neither be voiced nor tolerated by Indian politicians the reservations made by the Montagu-Chelmsford scheme to protect civilians, even in transferred services, would remain necessary.

M. Spahlinger's Treatment for Tuberculosis

A special meeting of the Parliamentary Medical Committee, on Thursday, July 2nd, received a report from five members of its committee who, though not as representatives of the committee, had visited Geneva between June 19th and 25th to investigate the Spahlinger method of treatment for tuberculosis. The report, which was a full one, was discussed at length by the Medical Committee, and several members who had previously investigated the Spahlinger system compared the party's experiences with their own. The committee had prepared recommendations, but in view of the fact that M. Spahlinger was expected in London at an early date for a conference, these recommendations were not pressed, and it was decided not to publish them at present.

The report to the committee was signed by Dr Watts, Dr Selter, Dr Vernon Davies, Dr Drummond Shiels, and Dr J. H. Williams. They stated that one of their number had special experience in the conduct of a bacteriological laboratory, and several had years of clinical experience with large numbers of tuberculosis cases. They stated that all questions put to M. Spahlinger and his fellow workers had been answered without reserve, and that experimental and clinical records were placed at their disposal. Each of the party examined about fifty patients who had suffered or were suffering from tuberculosis and had been or were being treated by M. Spahlinger's methods. The party found M. Spahlinger to be a highly skilled bacteriologist, with great knowledge of electrical and physico-chemical apparatus. They were satisfied that he was not actuated by personal or selfish motives, and had refused to allow his discoveries to be commercialized. The equipment of the Spahlinger laboratories was as good as the party had seen at any university.

Description of Method

The report presented by the members of the party which went to Geneva was to the following effect:

M. Spahlinger had produced two types of remedial for tuberculosis: (1) antitoxic serum to give passive immunity and to act as a directly curative agent and (2) vaccines or antigens made from cultures of specially exalted strains of tubercle bacilli and fractionated by a method devised by himself. He had devised methods whereby the tubercle bacillus could be stimulated *in vitro* to produce quantities of virulent and differing acetoxins. He stated that the bacillus did not ordinarily produce toxins of this kind in culture media, and only threw these out when its life was threatened. At certain regular intervals he subjected the cultures to physico-chemical conditions which proved irritative or harassing to the organism. For example, a culture was maintained under ordinary laboratory conditions at 37° C. for twenty-one hours out of the twenty-four, and the temperature was then raised to 38° C. for the next three hours. During these three hours toxin was manufactured. At the end of the three hours period the temperature of the incubator reverted to 37° C., and continued at

that figure for another twenty-one hours. Analogous methods also used were lowering the temperature, freezing agitation and exposure to light. Spahlinger believed he had isolated at least 21 or 22 different toxins, obtained either as above (exotoxins) or derived indirectly from the bacillary bodies (endotoxins). One of these toxins produced erysipelatous nodules when injected into susceptible animals, another had a purely pyrogenic effect, and so on. He used each of these separately to immunize horses and to obtain a corresponding specific antitoxic serum. These serums he described as "partial" serums. A "complete" serum was one which contained a mixture of all the partial antitoxic serums, in addition to an antibrucella serum obtained by immunizing a horse with the micro-organisms which caused mixed infections and with massive cultures of tubercle bacilli killed by exposure to light. Spahlinger stated that cultures killed by heat or carbolic acid lost certain of their important specific qualities in the process. At present no complete serum existed, though there were still about eleven horses yielding partial serums. Vaccine or antigen preparations also were not obtainable in bulk, chiefly on account of insufficiency of staff, though a certain quantity could be got ready in six or eight months.

The treatment consisted of injecting antibodies subcutaneously two or three times a week, sometimes every day or even several times a day in very acute and advanced cases. The length of the treatment varied according to the gravity of the case. The particular class of serum used depended upon the type of case. For pulmonary tuberculosis there must be a preponderance of antituberculous. For surgical tuberculosis a preponderance of anti-endotoxin was found best and a mixture of serums prepared by the use of human and bovine strains of the bacillus was employed. Chronic and afebrile cases could be treated with vaccine and without antitoxins from the commencement. A complete clinical recovery could be brought about by the means of serum alone, but a relapse or a remission was probable until passive immunity had been converted into active immunity. In eliciting active immunity various antigenic solutions derived from bacillary protoplasm were injected separately into the patient. The total treatment extended over about six months though advanced cases might require a second course of treatment. Spahlinger stated that he had devised a method whereby repeated doses of serum up to 20 ccm could be given to cases without causing anaphylaxis.

Up to the present about 600 cases were known to have been dealt with by M. Spahlinger and at least 250 could be traced and examined. A number were Russian prisoners of war who were detained in Switzerland and had disappeared.

The party reported that they had examined about 50 patients, some cured and well, some partially cured and in process of recovery, and some who were just commencing treatment. Amongst the latter were several of the gravest severity, which by no means of treatment at present known to science could be expected to recover. The clinical records of certain cases showed that persons who now appeared perfectly fit and well were originally suffering from an advanced stage of consumption. When the party saw them the only evidence of their original condition detectable was some patchy dullness indicating where the lungs were healed by fibrosis. There were no moist or adventitious sounds of any kind and the temperature was normal. The sputum examined and reported upon by independent medical observers attached to hospitals etc. was negative. Some of these people were following unhealthily occupations in a very bad environment yet remained well. Scarcely any of the patients had been treated by Spahlinger's remedies under suitable hospital or sanatorium conditions. Many of them remained at work though their temperature was well above normal. Cases of healed surgical tuberculosis were also shown though the pulmonary cases were the more striking. A number of cases had been treated from eight to twelve years ago and had remained well without relapses during that time.

The party came to the conclusion that on the evidence presented a *prima facie* case had been made out for the Spahlinger treatment. They recommended that an exhaustive trial should be made under test conditions as soon as it was possible to obtain a sufficient quantity of the serum and of the vaccines. The report then referred to the financial difficulties of M. Spahlinger which were declared to be acute. Progress in manufacturing serum and the report of the party continued to be plainly understood by the public that there was no hope of securing treatment by Spahlinger's method at the present time and that it would be useless for patients to apply for treatment. The only method of facilitating the development of the treatment was by the immediate provision of funds followed in some months time by the distribution of enough of the remedy for a really satisfactory test to be made under the strictest conditions.

After a discussion, during which some members of the Parliamentary Medical Committee expressed the view that the matter lay outside its province, the following resolution was adopted:

That the Parliamentary Medical Committee has received with much interest the account of the visit to the Spahlinger establishment which the five members of the committee have drawn up not as a delegation from the committee but as private individuals. The committee are of opinion that a *prima facie* case has been made out for further investigation but the committee resolve that they cannot as a corporate body, take any action in the matter.

Indian Medical Service.—On July 6th Sir Pichay Luce asked the Under Secretary for India if the Government had yet arrived at

conclusions as to the future of the Indian Medical Service and whether it was its intention to carry out the proposals of the Lee Commission in this respect. Especially in the matter of establishing provincial medical services the members of what would not be under the control of the Secretary of State for War. Under Secretary for India replied that the Government of India's proposals were now under the consideration of the Secretary of State who hoped to arrive at early decisions and would make no further statement could be made.

The Harnett Case.—Lord H. Cavendish Bentinck asked the Minister of Health whether he would advise the Government to pay to Mr. William Smart Harnett an adequate sum in compensation for his detention in various mental hospitals in regard to the fact that Mr. Harnett had been found by a jury to have been sane when detained by Dr. Bond and for the rest of his detention and that this opinion had not been upheld by either the Court of Appeal or the House of Lords by which tribunal Mr. Harnett's case had been heard. Mr. Neville Chamberlain replied that he did not think that any claim for compensation out of public funds could be substantiated. No event of the Crown was involved other than Dr. Bond and as a new trial had been ordered against Dr. Bond the matter was still *sub judice*. The Lord Chancellor in his judgement dismissed Mr. Harnett's appeal expressly pointed out that it was not in fact proved at the trial nor found by the jury that the appellant was of sound mind between the date of his alleged detention by Dr. Bond and his subsequent escape from custody.

Insurrection in Foul.—On July 7th Sir Kingsley Wood informed Mr. A. Alexander that the Minister of Health hoped that the Public Health (Insects) Bill in Foul etc. for alterations would be submitted to Parliament before the summer adjournment. Considerable modifications had been made in the original draft and a full discussion between the officers of the Ministry and the interests involved. The coming into force of the regulations would be postponed to enable necessary adjustments to be made by the trades concerned and during that period a decision might be arranged in the House of Commons if there was a general election for it.

Rock Drilling.—On July 7th Colonel Lane-Fox (Secretary for Mines) informed Mr. D. Grenfell who asked a question as to the prevalence of phthis among men engaged in rock drilling by the use of compressed air machines that he was not in a position to give any general conclusions. The inquiry that had been made was confined to three mines. Its result was to support the apprehension that in the three mines rock drilling might be dangerous to health. He had arranged for a more extensive inquiry at once. The inspectors were taking up the question of precautionary measures at the three mines.

Ophthalmic Benefit.—Mr. Bennett asked the Minister of Health whether as a result of the new model scheme for the provision of ophthalmic benefit by approved societies the charge for ophthalmic examination of the applicant had been raised from 5s. the fee paid to qualified opticians to £1 1s., the fee charged by ophthalmic surgeons. Mr. Chamberlain said he was aware that the cost under the new scheme might in certain cases show the increase stated by Mr. Bennett but there would be no charge for the insurance doctor's recommendation, and the new arrangements had been generally accepted by the approved societies.

Medical Sanitary and Research Expenditure in Tanganyika.—Mr. Amey, the Colonial Secretary, on July 6th told Mr. Barclay Harvey who asked the amount spent on medical and sanitary services and research work by the Germans in Tanganyika in 1913 and the corresponding figures in 1923-24 that the amount provided in the German estimates for 1913 was approximately £99,000 converting the mark at 20 to the £. This did not include expenditure by certain local bodies to which grants were made for a variety of purposes including expenses connected with hospitals and sanitation which were not shown separately in the estimates. The amount provided for similar services in the estimates for 1923-24 was approximately £116,700, which included all expenditure on buildings.

Notes in Brief

Of fourteen local authorities mentioned by the Chief Medical Officer of the Ministry of Health in his report for 1923 as not providing medical inspection for visual defects in school children all save one are providing or have proposed to provide such treatment.

The Ministry of Health is aware of the pollution of the river Lea with sewage and is making efforts to obtain proper treatment and disposal of the sewage. Two of the local authorities are improving their disposal works and a bill is before Parliament for taking the sewage of two others into the London main drainage system.

It is not the intention of the Government to take any further steps with regard to the proposed International Convention for bidding night baking. Its decision not to ratify has been previously announced. Night baking has been prohibited in fifteen European countries.

The Admiralty has reduced the number of landing sick berth attendants by forty-nine as dental attendants in harbour establishments formerly rated as such are being replaced by civilians.

Sir Kingsley Wood announced that before sanctioning the setting up of institutions by local authorities for the use of artificial light the Minister of Health would satisfy himself that a doctor experienced in this work was available.

Obituary

T MARK HOVELL, F R C S D,

Consulting Aural Surgeon, London Hospital. Consulting Surgeon, Hospital for Diseases of the Throat, Golden Square

THE death of Mr Mark Hovell, on June 30th, severs another of the few remaining links with Morell Mackenzie and the beginnings of laryngology in this country. He was the son of Dr D de Beidt Hovell of Clapton, at one time president of the Hunterian Society, and received his medical education at the London Hospital. He took the diploma of M R C S Eng in 1875 and the F R C S Ed in 1880, and was appointed surgeon to the Hospital for Diseases of the Throat, Golden Square. He assisted Sir Morell Mackenzie in the preparation of his *Diseases of the Throat and Nose*, and in 1887 Mackenzie invited him to take medical charge of the Crown Prince Frederick. Mr Hovell remained in constant attendance on his illustrious patient after he became emperor, until his death in 1888, and was decorated at his accession with the Order of the Crown. On his return to London he was appointed aural surgeon and lecturer on diseases of the throat at the London Hospital. He was president of the Section of Laryngology and Otology at the Annual Meeting of the British Medical Association in 1901, and president of the Section of Laryngology of the Royal Society of Medicine in 1917. Mr Hovell was the author of a well known book on *Diseases of the Ear and Naso-pharynx*, which reached a second edition, and he published many articles on otolaryngological subjects in this and other medical journals. Last year he published an interesting and practical work on *Rats and How to Destroy Them*, founded on experience gained at his country house near Hatfield, this volume received high praise from the scientific and other journals at home and abroad, and is recognized as the standard work on the subject.

Although Mr Hovell's characteristically conservative views on the tonsil gave rise to a good deal of discussion more than once, he was admired by his colleagues as a surgeon of very wide experience and sound judgement, notable for his thoroughness and common sense.

He married in 1905 the Hon Margaret Cecilia Bateman-Hanbury, daughter of the second Lord Bateman, and leaves one son.

CHARLES F HARFORD, M A, M D Cantab

WE regret to announce the death of Dr C F Harford on July 4th at his home in Harpenden. He was well known for his practical interest in a variety of subjects—medical missionary work, temperance reform, tropical medicine, ophthalmology, and (during recent years) psychotherapy.

Charles Forbes Harford was born at Keswick in 1864, the youngest son of the Rev Canon Harford-Battersby. From Repton he went to Trinity College, Cambridge, and studied medicine at St Thomas's Hospital. In 1889 he obtained the diplomas of M R C S and L R C P Lond, and graduated M B, B Ch, proceeding M D in 1892. After acting as ophthalmic assistant at St Thomas's and Moorfields, he went out, in 1890, as a medical missionary to Lokoja, West Africa. Three years later he returned to England, and was appointed principal of Livingstone College, Leyton, which he had helped to found in order to supply elementary medical instruction for candidates for the mission field. He held that post until the outbreak of war, when he obtained a temporary commission in the R A M C. From 1914 to 1919 he served in France and England as ophthalmic specialist with the rank of captain, and after demobilization he carried out corresponding duties under the Ministry of Pensions. Since the war he had acted as oculist to school children under the London County Council and the Herts County Council, and as refraction assistant at St Bartholomew's Hospital.

For fifteen years Dr Harford was secretary to the medical committee of the Church Missionary Society, and advisory physician to the society, he had been joint secretary of the Royal Society of Tropical Medicine and

Hygiene, and instructor in health to the Royal Geographical Society, of which he was a Fellow.

Throughout his career he worked for the cause of national sobriety, and in 1919 he was secretary to the Church of England Temperance Society. He was a fluent writer, and many articles and letters from his pen appeared on this subject, as well as on psychotherapy and on psychology in its relation to problems of vision. His book, *Mind as a Force*, appeared last year, and was reviewed in our issue of November 29th, 1924. He served for a time as editor of *Climatic*.

Dr Harford married Adeline, daughter of Mr William Clapton, F R C S, and had one daughter. The funeral took place at East Hyde on July 7th. A memorial service will be held at Livingstone College, Leyton, on Tuesday, July 14th, at 4.30 p.m. The Bishop of Barking will officiate. Friends are invited to attend.

We are indebted to Mr W McADAM ECCLES for the following appreciation. My friendship with the late Dr Charles F Harford, known then as Charles Harford-Battersby, dates back to 1887, when, as a student at St Thomas's Hospital, he was a fine cross-country runner, out-distancing most of us from St Bartholomew's. He qualified in 1889, and in 1890, to the surprise of some, he went out as medical missionary for the Church Missionary Society to Lokoja, West Africa. It was his sojourn in this mission field which gave him his insight into the need of elementary but sound knowledge of health matters for those proceeding to spheres where lurked serious dangers to health, and he spent a large part of the rest of his life in seeking to remedy such a lack of knowledge. In 1893, in association with the late Dr Harry Guinness and myself, he founded Livingstone College and became its first principal. Here hundreds of men and women have received an elementary training in medicine, surgery, hygiene, nursing, and cooking which has stood them in good stead when alone in the outposts of empire, miles upon miles away from qualified medical aid. Later his work as secretary of the medical committee of the Church Missionary Society, and physician to the society, so thoroughly carried out, led to far-reaching improvements in many branches of the society's work abroad. Keenly interested also in social reform, particularly in the question of the abuse of alcohol, he acted for a while as secretary of the Church of England Temperance Society, and of the Native Race and Liquor Traffic United Committee, and was diocesan reader in London, St Albans, and Chelmsford dioceses. Fearless, apt at times to be dictatorial, but always because he felt that the right must be championed, and imbued with great energy, everyone who came in contact with him could not but feel that they had met a true and earnest man, keen to help where his knowledge was useful, ready to draw swords with those from whom he differed, but always as a Christian gentleman. With his work in ophthalmology and tropical medicine others more competent will doubtless deal. Working, writing, speaking, and active to the very day before his death, all his friends will say, "Well done, enter into rest."

R H SCANES SPICER, M D Lond,

Consulting Surgeon for Diseases of the Throat, St Mary's Hospital

WE regret to record the death, in his 69th year, of Dr Robert Henry Scanes Spicer, which took place on June 18th. He was the son of Dr Scanes Spicer of North Molton, Devon, and received his medical education at St Mary's Hospital, where he gained an entrance scholarship in natural science in 1877, and was demonstrator in anatomy in 1879. In 1877 he graduated B Sc in the University of London, and he took the diplomas of M R C S Eng and L S A in 1882. He took the degree of M B Lond, with honours, in 1882, and proceeded M D in 1885.

Dr Scanes Spicer held the post of medical superintendent of Fulham Poor Law Infirmary from 1884 to 1888. He studied in the leading throat clinics in Vienna, Berlin, and Paris, and was appointed surgeon for diseases of the

throat at St Mary's Hospital in 1888, an appointment which he held until 1908, when he was made consulting surgeon. He took a leading part in founding the Laryngological Society of London, and was jointly the first secretary, and subsequently vice-president, he was also one of the founders of the Otological Society of Great Britain. In the British Medical Association he was honorary secretary of the Section of Laryngology in 1890, vice-president in 1895, and president in 1900. He was also a Fellow of the Royal Society of Medicine.

He contributed an important original paper on cancer of the throat to this JOURNAL in 1909 and several other papers on the same subject were published in the *Proceedings of the Royal Society of Medicine*. He held interesting and original views on posture and respiration as causative factors, which, however, were not endorsed by his colleagues. Dr Scanes Spicer was an excellent laryngeal and nasal operator, in fact, the widely employed Caldwell-Luc operation for empyema of the antrum of Highmore might equally correctly have been called the Scanes Spicer operation, as he introduced it in London simultaneously with Caldwell in New York and Luc in Paris. He retired from practice in 1913 owing to impaired health, but returned to work under the Ministry of Pensions until a more serious breakdown in 1922. He leaves a son (who was head boy at Eton in 1917, and afterwards took a first class in the Classical Tripos at Cambridge) and two married daughters.

ERIC SINCLAIR, M.D.,

Inspector General of Mental Hospitals, New South Wales.

Dr. ERIC SINCLAIR, Inspector-General of Mental Hospitals in New South Wales, who died recently while on a tour of inspection, was born in Greenock in 1860, and received his medical education at Glasgow University, where he graduated M.B., Ch.M. in 1881 and M.D. in 1886. After serving as house surgeon and house-physician to the Western Infirmary, Glasgow, he entered the New South Wales State Public Service in 1882, and two years later assumed control as medical superintendent of the Gladstone institution. In 1898 he succeeded the late Dr. F. N. Manning as Inspector-General of Mental Hospitals, which post he continued to hold up to the time of his death. He took great interest in improvements in the treatment of insanity, and instituted a system of training of nurses and attendants. The establishment of a chair of psychiatry in Sydney University was largely due to Dr. Sinclair's continual advocacy. He further instituted in New South Wales the system of admission of voluntary patients to mental hospitals. He is survived by two sons, both of whom are members of the medical profession.

Dr. H. C. McDONNELL writes

Eric Sinclair, who passed away so dramatically in the train on May 19th—literally in harness, as he was on his way to inspect the new mental hospital at Orange—was a man of very exceptional character and attainments. He had for some twenty-seven years shouldered alone the whole of the organizing and development work, as well as the administration, of the Lunacy Department of New South Wales, and, in addition to this, during the later period of the great war took on the onerous and anxious work of principal medical officer of No. 2 Military District (New South Wales), with the rank of lieutenant-colonel.

He was a man with great capacity for detail, and he loved to plan out for himself the minutest specifications of the new buildings he was projecting. He was essentially an up-to-date man, and a desire for the amelioration of the lot of those suffering from mental illness with a clear view of possibilities of improvement in their treatment, especially in the direction of removal of restrictions, was an outstanding feature of his administration of an office which is at present constituted, necessitates great self-reliance and responsibility in the holder. Dr. Sinclair reached the compulsory retiring age early in the present year, and had contemplated giving up his office at the end of last year, as he suffered from some cardiac disability, but at the request of the Government he consented to

carry on for another twelve months, and it was while endeavouring to do so that death cut him off before he had even tasted any of the leisure his long and arduous service to his adopted country had earned for him, for he was a man who had never relinquished the reins of office to take a holiday since his appointment to his high position. It can be truthfully said that Eric Sinclair carried on, developed, and extended the great traditions of the Lunacy Department of New South Wales left by his predecessor in the office of Inspector General, the late Frederick Norton Manning.

THE LATE DR. W. J. J. STEWART

Dr. WILLIAM BUTLER writes. A kindly person, a humane doctor, unselfish, upright, and straightforward, Stewart was beloved of his friends, endeared to his patients, trusted and respected as an official. A loyal colleague, his sincerity impressed those who had the privilege of working with him, while his modesty, his unobtrusive strength of character and distastefulness of the loud and thrusting manners so much the vogue of seelers after place, singled him as one who came to his own in virtue of his innate fitness for the office. He so fully and satisfactorily filled the medical superintendent of the Wilkesdon Hospital he had scope for abilities naturally fitting for the position which a long experience in hospital administration and a wide knowledge in the diagnosis and treatment of infectious diseases enabled him to fill with exceptional success. In private life he was esteemed and loved no less than he was respected and admired as a public servant. He was a keen and good sportsman with wide and cultured sympathies, fond of outdoor pursuits, deeply interested in what is known as nature, and his varied appeals to those who were happy to be numbered among his friends will be missed by a privileged circle who will ever treasure his friendship. To his widow, left with a loving memory, the deepest sympathies are widely extended.

Medico-Legal.

ACTION FOR NEGLIGENCE AGAINST MEDICAL OFFICERS

THE jury disagreed in the action brought in the King's Bench Division by Mrs. Mary C. Venn of Thornton Heath, on behalf of herself and her children, against Dr. R. Veitch Clark, former medical officer of health for Croydon, and general medical superintendent of the Croydon Borough Hospital, Dr. J. M. Todesco, resident medical officer of the hospital, and Dr. G. W. Elder, formerly assistant resident medical officer of the hospital, for damages for alleged negligence in the treatment of her late husband, Mr. William E. Venn, a notary public practising in the City of London. The jury, however, unanimously exonerated Dr. Veitch Clark of any negligence.

The claim which was brought under the Poor Persons Rules came before the Lord Chief Justice on June 23rd and the hearing lasted five days. Sir Henry Maddocks, K.C., and Mr. B. M. Goodman appeared for the plaintiff, and Mr. A. Neilson, K.C., and Mr. T. Carthew appeared for the defendants.

The plaintiff alleged that when her husband was recovering from scarlet fever in 1922 he complained of pain in his leg, and his doctor diagnosed a deep-seated abscess. Mr. Venn was removed to the Croydon Borough Hospital on March 18th, where the plaintiff alleged his complaint was improperly diagnosed as scarlatinal rheumatism until April 25th when Dr. Clark ordered an operation. It was alleged that the operation was too late, and the patient died on June 15th.

The defendants denied negligence.

Sir Henry Maddocks, in opening the case, said that Dr. Milson of Thornton Heath diagnosed the complaint as a deep-seated abscess. The day after the patient was admitted to the isolation hospital Mrs. Venn told Dr. Elder this but Dr. Elder replied that in his opinion, Mr. Venn was only suffering from scarlatinal rheumatism. Mrs. Venn also told Dr. Todesco who said he thought it was a case of mind over matter, and that if Mr. Venn ceased to worry he would soon get better. On April 24th Mrs. Venn saw Dr. Clark, who examined her husband and ordered an operation, which was performed at the Croydon General Hospital on April 26th, a deep-seated abscess being found at the place where Dr. Milson had diagnosed it to exist a month previously.

Dr. E. G. D. Milson, in his evidence said there were medical means by which the presence and locality of a deep-seated abscess could be more or less definitely ascertained, and neglect of such an abscess might result in blood poisoning and death. It would take two or three weeks to produce an abscess of the size of that found when Mr. Venn was operated upon. Cross-examined, Dr. Milson said the hospital authorities appeared to have diagnosed

diphtheria in Mr Venn when he was admitted, and a septic throat might have accounted for his high temperature, but that would not relieve the medical attendant from considering the thigh rheumatic pain was very frequent after scarlet fever.

Mr Neilson K.C. in his opening, said Dr Milson had not suggested that an operation was necessary on March 18th. He sent Mr Venn into hospital for observation, and the reports showed that Mr Venn was carefully observed and that he made no complaint about his leg until April 16th. The trouble was then diagnosed as of a rheumatic nature and nobody could have said that the diagnosis was wrong. Later reports disclosed no complaint about pain in the leg, and on April 22nd inflammation first appeared.

Dr Veitch Clark, in his evidence, said he was not in charge of the patients at the hospital but visited them at the request of the resident medical officers. He was now medical officer at Manchester. When he saw Mr Venn on April 25th he found his leg swollen, red, and tender, and coming to the conclusion that there was an abscess he instructed the medical officers to call in a surgeon. He was of opinion that pus had not been present more than two days and that it could not have been discovered earlier than, possibly the evening of April 23th.

Dr Elder, now medical officer of the Manchester Corporation Sanatorium, said the day following Mr Venn's admission to the scarlet fever ward he examined him, and diagnosed diphtheria. He found Mr Venn suffering from a swelling on the right thigh and Mr Venn told him he was a martyr to rheumatism and that the rash over the swelling was caused by a hot water bottle. He was never told that Mr Venn was suffering from a disease of the leg.

Cross-examined he never diagnosed deep-seated inflammation, but the patient had such treatment as would relieve either a burn or deep-seated inflammation.

Dr Todesco, in his evidence, said on Mr Venn's admission he diagnosed scarlet fever and diphtheria. There was some redness on his right thigh but he (the witness) did not make a diagnosis of it. It was consistent with having been caused by a burn. Mrs Venn told him her husband had been treated for rheumatism, rheumatism was a common complication of scarlet fever. Mr Venn's condition on admission was not consistent with his having a deep-seated abscess.

Cross-examined he did not remember telling Mrs Venn that it was a case of mind over matter, and that if Mr Venn ceased to worry about his leg he would get better.

Dr F. L. Adams, of Croxson, said he saw Mr Venn on April 25th and found him suffering from a large fluctuating abscess. In his view, the formation of the abscess had only begun four or five days before.

Nurse Corney, who was in charge of the double infection ward at the Croxson Borough Hospital in March and April 1922, said on April 18th Mr Venn complained of pain in the leg but there was nothing to be seen. She first saw inflammation on April 20th and by April 22nd the leg had become very inflamed. On admission, Mr Venn told her he had had rheumatism, and that he had been burned with a hot water bottle.

Dr William Hunter, C.B., senior physician to the London Fever Hospital from 1880 to 1925, said he had carefully considered the Harris reports, and other documents relating to the case and he was of opinion that on Mr Venn's admission nothing surgical could have been done. He should have marked the case 'Queer, rheumatism or query something else.'

The jury disagreed.

The Lord Chief Justice asked Mr Neilson K.C., if he was willing to take a majority verdict, but Mr Neilson replied that he was for the defendants.

The Lord Chief Justice: Then you are not willing.

ALLEGED NEGLIGENCE AT CONFINEMENT

In the King's Bench Division, before Mr Justice Sinfrey on July 1st, the jury gave a verdict for the defendants Dr J. L. W. Kitching, Dr R. C. P. Whitcombe, and Dr J. Hale, who practise in partnership at Cobham, in an action brought by Mr A. E. Sherlock, an under gardener employed at Cobham on behalf of himself and his three children, for alleged negligence in the treatment of his late wife in childbirth.

Mr B. B. Stenham appeared for the plaintiff and Mr W. A. Jowitt K.C. and Mr T. Cartwright appeared for the defendants.

Mr Stenham in his opening said the deceased woman was strong and healthy and normal in every way. She had a baby 2 years old, and in 1923 she became aware that she was going to have another. The district nurse was communicated with and Dr Kitching was to be the doctor to attend her at the confinement which was expected on March 7th 1924 but actually occurred on March 12th. The plaintiff's employer Mrs de Jonge, a Dutch lady with some years of nursing experience, observed that the deceased had a certain amount of swelling above the ankles for some eight weeks prior to the confinement and she took tests of the deceased's water and found albumin. She told Dr Kitching who replied that he had found no albumin worth mentioning in his tests, and also that, in his opinion, the patient's physical condition was quite satisfactory but her mental condition was something different. Dr Kitching also declared that Mrs de Jonge had been carrying out tests in front of the patient and marking her beliefs she was ill. Later the patient became lethargic, and Dr Kitching caused her removal to Epsom Infirmary where she died on March 24th. Counsel said the deceased died of eclampsia but if her symptoms had been carefully watched at an earlier stage, and if Dr Kitching had not got a preconceived

notion of what was the matter, she would have had a proper diet and in - - - did not have died.

The - - - said he did not allege anything against Dr Whitcombe, but he alleged negligence against the other two partners. Mrs de Jonge did not prescribe diet for his wife but she out-nursed her with his consent.

Mrs de Jonge, cross-examined, admitted that as the result of another case in which she had interested herself she did not think much of Dr Kitching after that. She had put the plaintiff funds for that action, but she denied encouraging him in it. There was a time when he intended dropping it and she left him perfectly free to drop it. When Dr Kitching reprimanded her for interfering in the case she admitted that she cried and ran away.

Dr Robert Maxwell Trotter of London said, in his opinion Dr Kitching ought to have diagnosed eclampsia on March 17th, 1924. Cross-examined, he said, if Dr Kitching found no albumin before the confinement, in his opinion up to the 16th Dr Kitching had done nothing wrong. If no albumin was found on the Tuesday, he did not think it could be said the patient was suffering from eclampsia.

Dr W. G. Donald of Walthamstow said from the evidence he had no doubt whatever that the deceased died from puerperal eclampsia. Mrs de Jonge's tests of albumin appeared to him to have been normal and proper tests. He did not agree that the symptoms were such as were likely to be those of encephalitis.

Dr Guy M. Kendall, assistant medical officer at Epsom Infirmary, said he made a *post mortem* examination and found death to be due to eclampsia and cerebral.

Mr Jowitt K.C. in his - - - did not guarantee results and he submitted - - - for the jury to

say a case of negligence had been made out against defendants. Mrs de Jonge was interested in medicine and had that little knowledge which was such a dangerous thing. She was, no doubt, one of the most generous unselfish devoted persons one could wish to meet but he hoped the result of this case would be to hold up a finger of warning to persons against interfering in any way with a case in which a doctor was concerned. It was no part of his case to show that the cause of death was encephalitis lethargica but he would call eminent men who would say that in the light of what they now knew it was more likely to be encephalitis lethargica than eclampsia.

Dr Kitching cross-examined said Mrs de Jonge's tests were not of the slightest value. He thought she was a nuisance. She had no standing in the sick room at all. The deceased's symptoms pointed to a cerebral and mental condition. He, however, had not made up his mind to anything. He thought the deceased's condition entirely due to the atmosphere created about the house and that she was being harried into a mental state. One of the things he objected to was that Mrs de Jonge while discussing the patient's condition practically waved her test tube in the patient's face.

Dr Whitcombe in his evidence said the patient seemed upset and worried. There were several persons in the sick room and the noise was so great that one could scarcely hear oneself speak. There was no symptom of eclampsia.

Dr Hale in his evidence said he and Dr Kitching together examined a specimen of the deceased's urine and found no albumin. When the deceased was removed to the infirmary he wrote to the medical officer asking if he thought it was a case of encephalitis lethargica. He at no time agreed with Dr Kendall that death was due to eclampsia.

Mrs Wakefield, certified midwife who attended the deceased during and after the confinement, said she had had experience of eclampsia, but there were no symptoms in this case which led her to suspect the patient had eclampsia.

Dr J. P. Hedley, obstetric physician to St. Thomas's Hospital, London, said the case in no way resembled eclampsia.

The jury found for the defendants and judgement was entered accordingly.

Universities and Colleges

ROYAL COLLEGE OF SURGEONS OF ENGLAND

ELECTION TO THE COUNCIL

At a meeting of the Fellows on July 2nd for the election of three Fellows into the Council in the vacancies occasioned by the retirement in rotation of Mr V. Warren Low, Mr James Sherren, and Sir John Lynn Thomas, Mr Sherren and Sir John Lynn Thomas were re-elected and Mr Arthur Henry Burgess of Manchester was elected. 964 Fellows voted including 172 Fellows resident out of Great Britain and Ireland, 961 sent ballot papers through the post and 3 voted in person. The result of the poll was as follows:

Candidates	Votes	Plumbers
ARTHUR HENRY BURGESS	462	48
JAMES SHERREN	441	14
SIR JOHN LYNN THOMAS	406	7
Victor Bonney	361	19
Vincent Warren Low	332	12
John Percy Lockhart-Mummery	243	11
Herbert John Paterson	232	18

Three voting papers were found to be invalid, and in addition three voting papers were received too late.

DEATHS IN THE SERVICES
Lieut Colonel George Tucker Thomas Madras Medical Service (ret.) died in London on June 3rd. He was born on September 25th 1851 the son of the late Rev John Thomas of the Church Missionary Society, Tinnelly and after taking the M.R.C.S. and L.R.C.P. Lond in 1873 entered the I.M.S as surgeon on March 31st 1875. He reached the rank of lieutenant colonel after twenty years service and retired in 1905. Almost the whole of his service was spent in civil employment at first in Madras where when resident medical officer of the Madras General Hospital he came into collision with the Provincial Government in a case which created a good deal of stir and interest in India, some forty years ago, and afterwards in Burma.

Medical News.

THE publication by the Stationery Office of the volume of general tables comprising population, housing, institutions, ages and marital conditions, education, birthplace and nationality, and the Welsh language, completes the series of volumes of tabulated statistics derived from the census of June, 1921. This final volume contains the aggregated figures of the sixty county volumes that have already appeared, and so renders possible the study of the census from a national standpoint. A certain amount of new matter has been added relating to populations of county court circuits and districts, seamen and fishermen not enumerated with the general population on census night are included, also persons in vessels or establishments under naval, military, or air force discipline outside Great Britain. The price of the volume is 13s., and it may be obtained from H. V. Stationery Office.

A FORTNIGHT ago a leading article was published giving an account of the difficulties which had arisen with regard to reciprocity of medical practice with Italy, and stating that an agreement had been signed under which full freedom of practice in Italy was accorded to British practitioners, the country undertaking to admit medical practitioners possessing degrees from Italian universities to the Foreign List of the Medical Register of the United Kingdom. We learn from Mr. Norman C. King, registrar of the General Medical Council, that the Council has been officially informed that the Italian Embassy in London has communicated to all the consular offices under its orders the regulations concerning the admission of British registered practitioners to the privilege of practising medicine in Italy and its dependencies. The new arrangement comes into force from the date of its signature (May 21st, 1925) without need for further ratification or approval.

THE Fellowship of Medicine announces that a course in the diagnosis and treatment of common diseases of the nervous system has been arranged by the West End Hospital from July 27th to August 14th. A vacation course will be held at the Prince of Wales's General Hospital from August 4th to 15th, including lectures and demonstrations in medicine, surgery, and special subjects, including mental diseases and fevers. At the All Saints Hospital there will be a special course in urological diseases throughout the month. From August 24th to September 5th the Queen Mary's Hospital, Stratford, will give an intensive course in medicine, surgery, and the specialties. The following special courses are announced for September: diseases of the chest, infants' diseases, dermatology, electrotherapy, ophthalmology, and an intensive course at the Westminster Hospital. Copies of the syllabus of each course and the programme of the Fellowship of Medicine may be obtained from the Secretary at 1, Wimpole Street, W.1.

AN announcement appears in our advertisement columns inviting applications for the appointment of two assistant medical officers for the Mental Hospitals Department under the New Zealand Government. The commanding salary is £615 per annum. Particulars may be obtained by sending a foolscap envelope to the High Commissioner for New Zealand, 415, Strand, W.C.2.

THE National Baby Week Council has held during the present week an Imperial Baby Week at Wembley Exhibition. On July 6th Dr. Mary Scherke presented prizes and certificates won in various annual competitions, including the Astor challenge shield for the best local baby week campaign in 1924, awarded to infant welfare centres.

The week film displays and lectures

At the Climatological Congress to be held at Davos from August 17th to 22nd the topic for discussion will be the significance of climate in its physical, physiological, and therapeutic aspects. Those desirous of contributing papers on any branch of the subject, or requiring details of the arrangements, should communicate with the Secretary of the Congress, Dr. Vogel, Eysen, Davos Dorf.

THE German Society for the Promotion of Morality, which represents the German Branch of the International Abolitionist Federation, is bringing before the Reichstag a bill for placing under supervision all persons who are insane, mentally deficient, or who, in consequence of mental, physical, and moral defect, are incapable of looking after themselves and are a danger to others. The supervision will be arranged at the public expense by order of the county court in a suitable family, institution, or workmen's colony.

THE annual dinner of past and present students of St. Mary's Hospital Medical School will be held at the Connaught Rooms, Great Queen Street, W.C., on Monday, October 5th, at 7.30 p.m.

THE St. Bartholomew's old students' dinner will be held on Thursday, October 1st, in the Great Hall of the Hospital, at 7.30 p.m. The chairman will be Mr. John Adams, F.R.C.S. The honorary secretaries are Sir C. Gordon Watson and Mr. R. M. Vick.

SUBSCRIPTIONS received at the Mansion House for the Metropolitan Hospital Sunday Fund reached, on July 6th, a total of about £51,000.

A VACATION course of instruction for qualified practitioners will be given again this year at St. Bartholomew's Hospital, beginning on Monday, September 7th, and ending on Friday, September 18th. Inquiries should be addressed to the Dean of the Medical College, St. Bartholomew's Hospital, E.C.1.

DR. GEORGE P. ALDRIDGE of Luton Bolton, has been appointed to the Commission of the Peace for the County Palatine of Lancaster.

DR. MOURIQUAND has been nominated professor of children's diseases in the Lyons Faculty of Medicine in succession to the late Professor Weill. Professor Gott of Munich has succeeded Professor Salge in the chair of children's diseases at Bonn.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, **British Medical Association House, Tavistock Square, W.C.1** on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the JOURNAL should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are: **VESEUM 9361 9362 9363**, and **9364** (internal exchange four lines).

THE GRAPHIC ADDRESSES ARE:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Atiology Westcott London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc.), *Atiology Westcott London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus Dublin* telephone 4737 Dublin) and of the Scottish Office 6 Drumsheugh Gardens, Edinburgh (telegrams *Asociate, Edinburgh*, telephone 4361 Central).

QUERIES AND ANSWERS

UNCERTIFIED LUNATICS

"P. & D." writes to ask for enlightenment as to a doctor's position with regard to uncertified lunatics. Sometimes (he says) individuals evidently insane walk into one's surgery and sometimes one visits families where insane relatives are kept at home, the relatives refusing to allow certification although the individuals in question are clearly dangerous while at large. What should the doctor do in such cases?

'EUPARAL'

DR. A. H. SKINNER (Beckenham) writes: On page 888 of the **JOURNAL** of May 9th in a review of Jordan's *Textbook of Histology* mention is made of a new mounting medium 'euparal'. I find difficulty in obtaining this.

The method of preparation of this mounting medium is described by Shepherd in the *Transactions of the American Microscopical Society* vol. 37 (1918) p. 131. We understand that 'euparal' can be obtained in this country from Messrs. Parry and Tallock, 14, Cross Street, Hatton Garden, E.C.1.

STREPTOCOCCAL INFECTION OF TONGUE

"G. P." writes to suggest to 'Peppercod' (June 27th p. 1201) that a Wassermann test should be made. In a similar case he has found it positive greatly to the surprise of both the doctor and patient.

INCOME TAX

L. B. C. has received an inquiry from the local inspector of taxes with regard to the deductions made for domestic servants' wages; he has deducted the estimated cost of food, etc., of one maid at each of the two houses used for the practice.

Our correspondent does not say what staff is employed at each house and a good deal must depend on that—for example, if to take an extreme instance, the staff kept is one resident

maid and one day girl, with occasional assistance it would seem to be unreasonable to charge the whole cost of the maid as incurred in connection with the consulting room, answering the inquiries of callers, and other strictly professional work. A useful working rule is that where two maids, with occasional assistance, are kept, the cost of one maid is probably a reasonable charge but beyond this it is not possible to give general indications. Where it can conveniently be arranged, a personal discussion with the inspector is often the best means of settling this type of question.

Expenses Incurred by Locumtenent

"STELLA" did some locumtenent work last year and incurred £6 in travelling to the hospital where the work was done. The inspector refuses to allow this expense as a deduction from the inclusive fee received.

* * The difficulty seems to be that "Stella" is not in general practice, and therefore cannot assert that the fees in question were earned and the expenses in connection therewith were incurred as part of his ordinary medical work. The locumtenent work was apparently an isolated matter, and, if treated as such, the expense of going to and from was not earned in the performance of the duty but in order to put our correspondent into a position to perform it. At the same time the expense of travelling from place to place is so natural to the performance of locumtenent work that we should have thought that the inspector would have allowed it, rather than take up what is a very strict and somewhat harsh attitude on the strength of the peculiar features of an unusual case.

LETTERS, NOTES, ETC.

SUMMER TIME

THE secretary of the Early Closing Association writes to say that during the past four years resolutions in favour of the permanent adoption of a six months summer time period have been passed by 1,000 municipalities, trade organizations, chambers of trade or commerce, athletic and other associations. Resolutions have also been unanimously carried at two public meetings at the Mansion House held under the presidency of the Lord Mayor of London, and at large meetings in Birmingham, Bradford, Bristol and Manchester. Deputations have also presented evidence as to the urgency of this matter to the Home Secretary and the second reading of the Summer Time Bill was passed in the House of Commons on March 13th last by 289 votes against 63. Notwithstanding the strong public opinion in favour of this measure and the sympathetic support of the late and present Governments the bill is still in abeyance. Unless public opinion is aroused the summer time period this year will end abruptly in the middle of the holidays—namely, in the middle of September—and at a time when the additional hours daylight from work and business is so much needed.

* * The British Medical Association as most of our readers know is strongly in favour of the proposal to make summer time a permanent measure. The Representative Body in 1923 passed a resolution expressing regret that summer time had been curtailed that year as it is of the opinion that summer time is beneficial to the health of the nation and the Council in February 1924 voted 5 guineas to the Early Closing Association towards the costs of its campaign for the extension of summer time and its permanent adoption.

URINARY INFECTIONS

DR HAROLD H. SANGUINETTI (London W) writes. In criticizing my paper on urinary infections Dr Irwin (July 4th p. 37) seems to assume a greater ignorance on my part of such infections than I feel is warranted by anything I wrote. The fact that the paper represents a much abridged version of a thesis presented and accepted for the D.M.O. I do not doubt accounts for some misunderstanding but even then it is obvious I did not advocate vesical lavage for definitely descending infections where the seat of the infection remained in the kidney or renal pelvis. What, however, I have suggested is that descending infections are not so frequent as is now usually maintained or alternatively, that in descending infections the focus in the kidney and renal pelvis in many cases clears up some considerable time before the bladder becomes free from infection. The persistent infection of the bladder can be satisfactorily treated with injections of collargol. I am naturally aware that the majority of acute cases clear up rapidly without the use of vesical lavage although in no inconsiderable proportion of these cases the clearing up is confined to the clinical symptoms and organisms persisting in the urine and leading to subsequent relapse. It will be noted that the majority of my cases were chronic cases among whom were at least a few who had undergone in the acute stage just the treatment Dr Irwin advocates. The fact is these cases have patient and medical attendant much trouble and with the treatment usually adopted are difficult to cure. When at a meeting of the Hunterian Society in the discussion of Sir John Thomson Walker's Hunterian Lecture on urinary infections I claimed that with collargol one could get 50 per cent of cures the lecturer—while I think doubtful of my

claim—agreed that a treatment as such it was claimed would give such results as worth careful consideration. My percentage of cures for a certainly small number of cases is considerably higher. We may I think leave it at that. When I have convinced myself that a suitable dilution of silver nitrate is certain, and not only 'probably' just as effective as collargol I shall use it in place of the latter. Meanwhile, I shall, for routine purposes, continue to use collargol.

THE JACOMETER

AN ancient Scottish university is said to have invented a Calorimeter for testing its doctors of divinity but in spiritual affairs we have just a man sober who could clearly affirm that "British constitutional prescriptions arbitrarily proposed puzzle the scientific American consulting his barometer, could forecast the next day a flow of liquor over the bar, and from the thermometer give the exact number of its labours." Now as we learn from the British Empire number of one of those publications devoted to the gratuitous postgraduate education of British doctors the American has invented a "jacometer" which shows the "disposable index" of a suspect and when a "jacometer" attachment has been affixed records accurately the appropriate period of debilitation. The instrument looks like a gas apparatus and a British entomologist thus hums its superiority to our rule of thumb methods.

In epochs of dublety
Green heral confusion
We'd test a man's sobriety
By British Constitution
We'd stand him perpendicular
Ask him for truly rural
Give arbitrarily standard
In verbiage in the plural
Dry Yankee scientific men
Have found a way much subtler
To tell if chauffs or other men
Have visited the latrine
Has he had coffee, milk or tea
Is tested by the jacometer
For their thanks the meter
Will clap on the jacometer

Then as his breath comes sighing out
It disposes a dial
And should it come to trying out
The needle stand his trial
They have a radiant plate beside
Tells starker from a lamp
And if one try the blue to hide
Shows every lit or limp
The psycho-analyst left behind
And vitamin an hormone to find
There's nothing new for man to find
Outside the land of Mormon
What need we think the final pains
What need for someone thicker
All other folks as give up first
When the Yankee gives up drinking
R C B

HOLIDAYS

DR W. B. DUNN (Medical Superintendent, Baldovan Institution Dundee) writes. I should be glad to know whether there is any reciprocity between public hospitals institutions etc. with regard to the holidays of members of staff passing from one to another. For example if a nurse who has had six months continuous work in one hospital passes directly to a post in another hospital without a holiday is the latter supposed to grant her the usual full holiday at the end of three months service?

COPPER CITRATE IN THE TREATMENT OF LEPROSY

LIEUT. COLONEL F. T. PALMER (Assam) writes to point out an error in our abstract on May 9th (p. 88) of a paper read by him. In one sentence copper sulphate was erroneously substituted for copper citrate. Colonel Palmer adds that copper citrate is used for intravenous injection in doses of 15 grains for an adult and is rendered soluble in small bulk by 4 grains of sodium citrate. The bismuth salt used by him is bismuth sodium tartrate which is generally given in 3 gram doses. Intramuscular injections were only employed in the initial experiments, and would not be suitable in so chronic a disease as leprosy, which requires very prolonged treatment.

SLOW HEART

SURGEON COMMANDER W. H. EDGIR R.N. writes. In connection with the question of slow heart action in athletes it may be of interest to state that I have constantly found a subnormal rate in the best Marathon runners in ships on which I have served. Four instances are present in my mind without reference to notes. Three were officers and one a private of marines. All were noted runners and capable of long sustained exertion and in all the pulse rate was between 54 and 64. I have come to regard the normally slowly acting heart as indicating special suitability for such exercises as running and boxing.

A DISCUSSION

MIR H. J. PATTERSON (London, W) writes. My attention has been called to a report of my annual hospital tea party in the *Daily News*. Although I was aware that the occasion was to be used for giving publicity to the hospital building fund I had no knowledge that personal allusions were to be made to myself. I much regret that in the report references were made for which I am in no way responsible and which are both unnecessary and undesirable.

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 37, 38, 39, 42 and 43 of our advertisement columns and advertisements as to partnerships, assistantships and locumtenancies at pages 40 and 41. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 16.

THE BRITISH MEDICAL JOURNAL · COMMEMORATIVE NUMBER

An Address

ON

THE OVERGROWTH OF SPECIALISM

DELIVERED TO THE ACADEMY OF MEDICINE IN TORONTO

BY

J. BASIL HALL, MCH, F.R.C.S.

PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION, HO ORAPY CONSULTING SURGEON, BRADFORD ROYAL INFIRMARY

I APPRECIATE very deeply the honour of being the first representative of the British Medical Association, since the affiliation between the British and the Canadian Medical Associations became an accomplished fact, to bring you our fraternal greeting and good wishes, and to address the members of our honoured profession in the great Dominion of Canada.

As I approached these shores I endeavoured to analyse my feelings. I found it difficult to realize that Ontario alone must be three or four times the size of the British Isles. As schoolboys we looked at our atlas and saw a map of England upon one page, and a map of North America upon another, but failed to grasp that vast difference of area of the two countries. Perhaps this was an early indication of our tendency in the old country to overestimate our own importance. Nevertheless, we do realize when we arrive at years of discretion that we are too self-centred, and we feel the necessity of cultivating a broader outlook, and a contact with the vigorous youth and newer views of our younger brothers.

As an illustration of our insular habit of mind, I would quote a passage from the writings of one of your own countrymen, a writer of whom you may be justly proud—Robert Service. The extract in which he gives us the rebuke we truly deserve is from his book *The Trail of Ninety-Eight*. The scene is laid in Dawson City, Yukon. A tall slim Englishman talking to the hero of the story, says:

How my old dad would stare if I could have him in Dawson City for a day! He would never be able to get things just in focus any more. He would be knocked clean off the pivot on which he has revolved these thirty years! Seems to me everyone is travelling on a pivot in the old country! It's no use trying to hammer it into their heads that there are more points of view than one! If you don't see things just as they see them, you are troubled with astigmatism!

Here is the opportunity, in your vast and wonderful country to readjust our convictions, and I thank you for helping to pull me off my pivot, and giving me the opportunity of seeing things from a new viewpoint.

Just as I was leaving the old country, the Council of the Royal College of Surgeons of England conferred upon me the honour of electing me a Fellow of their College. It is an honour of which I feel very proud, and I am deeply sensible of the distinction which it gives to me. My pleasure, however, has been very especially enhanced by the fact that I am sharing that honour with a Canadian, Professor Primrose of Toronto. I wish to extend to him my very hearty congratulations upon this recognition of his professional career, and to you, also, because he is one of your representatives in the great field of surgical science. I am sure you will forgive my insular prejudice when I say that I believe that it is one of the greatest surgical honours which can fall to the lot of any one of us, and in the years to come I shall always remember with much pride that my name had been associated with his.

THE NARROW SPHERE

Your President has proposed to me that I should say something to-night about some views which I recently expressed in my Presidential Address at the Annual Meeting of the British Medical Association. On that occasion I suggested that the modern development of specialism is becoming so great and so absorbing that we are in danger of losing sight of the value of that wisdom which can only be obtained by a laborious study extended over much wider fields.

Specialism has become a necessity in our modern scheme of medical practice, but surely it behooves us to be careful lest our profession becomes nothing more than a community

of craftsmen, each in his own water-tight compartment with little or no general knowledge of the problems which lie outside it. There is a growing tendency—I am speaking of England—to think that special practice confines a man's usefulness in life to one narrow sphere. It is said not infrequently, that a specialist is an individual who knows everything about his own particular subject, but nothing about anything else. That definition may be only a cynical gibe, but I cannot help thinking that it might become a sober truth, and I would urge that the attainment of a high degree of any ability can only be reached by those who realize that wide general knowledge must be the foundation upon which all professional eminence can be built. To be content to learn one thing, and one thing only, is surely a poor ambition. It may bring wealth and worldly success, but it very rarely brings real greatness. "Everything of something but something of everything" is such a motto which all of us should adopt.

In military service or in a great hospital, where large numbers of patients have to be looked after, work is essential. The cure of the patients is a matter of mass production. It is the only method by which a great output can be accomplished. We have learned that lesson from the great commercial enterprises in the world. There are thousands of human beings to-day who spend their lives in producing one important particular detail in the mechanism of some machine, or some process of manufacture. I have personal acquaintance with a man who earns a very handsome living in such an occupation. He can measure his work by a thousandth of an inch, but take him away from his one special employment, and you find him the dullest creature imaginable.

In the great iron and steel works in the city in which I was born there is a small group of men who earn large salaries by controlling the steam hammers which forge the wheels of locomotives and so forth. It is a great specialism, a craft which only a few possess. There appears to be a peculiar genius for this work, and I am told that it sometimes descends from father to son. The craftsmanship which these men display is wonderful, but take them away from their narrow specialism and you will find them very ordinary beings devoid of any interest in the progress of knowledge outside their own sphere.

Not very long ago I met a personal acquaintance who is a great expert in the textile world. His name is known in America, Australia, and many other countries. He had been spending a fortnight away from home, and I asked him how he had enjoyed his holiday. He said it had been very dull. He had just wandered about looking into the shop windows and reckoning up the cost of production of the materials displayed!

Specialism may be a great art, but it may be very soul-destroying. It may bring great wealth and notoriety, but it is a poor thing to live for, itself alone.

JOHN HUNTER: A CONTRAST

A few months ago I enjoyed the privilege of attending the Hunterian Festival at the Royal College of Surgeons of England, and witnessed the large gathering of nobility, aristocracy and drink in solemn silence to the immortal memory of John Hunter—an annual tribute which has been paid to his name for a hundred years. John Hunter was the very antithesis of modern specialism, a man who never neglected the opportunity to study any single object in nature lest he might miss some fragment of useful knowledge. What a wonderful life his was! He was a great surgeon, but surgery was only a very small item in an existence devoted

to the study of every problem in nature. Hunter began his dissections and preparation of museum specimens when he was 30 years of age. He died when he was 65 years old but during those intervening, thirty-five years he dissected and mounted upwards of five hundred specimens, illustrating the anatomy of innumerable types of invertebrate and vertebrate life, and he wrote manuscript descriptions of most of what he had done. During those thirty-five years he worked unceasingly to solve every problem in the animal and vegetable world, and his classical operation for incision remains to this day as one of the most perfect deductions from scientific observation applied to a practical use.

Stephen Paget, in his *Life of John Hunter*, reproduces one of his letters, written to a friend in Africa a few months before his death:

"There could be no better example than this letter of the vehement energy of Hunter's life. In his old age, full of suffering, overworked, and close to death, he was yet writing, to Africa for swallows, ostrich eggs, a crane, cuckoos, a young lion, everything connected with the bee tribe, chameleons and any other beast or bird."

While he was thus intensely intrigued with a human desire for general knowledge, he was Surgeon General to the Army, Inspector-General of Hospitals, Surgeon to St. George's Hospital, Surgeon Extraordinary to the King, and busily engaged in a great consulting surgical practice in London.

THE WIDER OUTLOOK

At the same festival, when I listened to the speech of the President, Sir John Blund Sutton, a speech full of wit, and a versatility which betokened a lifelong devotion not merely to the specialism of abdominal surgery, but to the study of comparative anatomy and zoology and the whole life history of mankind, I realized that his specialism had only played a very small part in placing him in the proud position he occupies to day. A great surgeon undoubtedly, but something much more than that—a man of wide scientific general knowledge, acquired by an endless study of human and animal life.

Only a few weeks later I was present at the funeral service of Sir Thomas Clifford Allbutt, Regius Professor of Physic in the University of Cambridge who died in his eighty-ninth year, a great scholar, and full of honours. He began his career as a classical scholar at King's College, Cambridge, and subsequently obtained first-class honours in natural science. Throughout his long life he never ceased to interest himself in any subject which might promote general knowledge. He introduced the clinical thermometer, which is used to day throughout the whole world. In 1871 he emphasized the value of the ophthalmoscope in the diagnosis of cerebral and renal disease. In 1873 he read before the Royal Society his paper on the effects of exercise upon bodily temperature. He subsequently edited a *System of Medicine*, which is one of which the medical literature in any language might be justly proud, and his work upon blood pressure, and the effect of overstrain upon the heart, is of great scientific value. It has been truly said of him that he was a charming speaker and a graceful writer. Faults of literary expression and logical arrangement vexed his soul. Truly a great physician, but something much more than that—a great scholar and scientist, and a very perfect English gentleman.

Is there any need for me to recall the life-work of such scientific giants as Pasteur, Lord Lister, or Sir William MacEwen? Do we not remember them as great men, who toiled unceasingly to promote general knowledge? Great men who required profound wisdom in an unlimited field of study, never doubting that every fragment of general knowledge would find its place in our scientific progress. Not so very long before the late Sir William MacEwen's death I was talking to him about the growth and shedding of the antlers of deer, a subject in which we were both interested, and one upon which he wrote a most absorbing book. Long after it has been forgotten that MacEwen introduced osteotomy to cure genu valgum that book will remain as a record of truth scientific research. Do any of us to day know anything about Lord Lister as a surgical "specialist"? His work as an operating surgeon is forgotten in the light of his labours in the wider fields of his researches. As an artist he is already forgotten, but as a scientific worker his name lives for ever.

WISDOM OR TECHNIQUE?

Is the modern trend of medical practice likely to produce such men as I have mentioned—men who were not interested in specialism but who were interested in the whole of life, whose mental activities were directed towards the sciences of observation and research. Is it not possible that we are all specializing too much and reducing individual usefulness to very narrow limits. The human body is a complex structure composed of many organs, but there is a vital interdependence among them, which is essential for the maintenance of the whole. It is really desirable that every man should train himself to combine his knowledge to only one narrow branch of medicine or surgery, and believe that a perfect technique can accomplish everything.

The President of the Medical Society of London recently touched for the accuracy of the following anecdote:

A patient, worried with abdominal pain and obsessed with the popular dread of appendicitis, consulted a specialist who removed the appendix. The pain remained and she applied to a generalist who removed the right ovary. The pain remained and she applied to someone who had a great reputation for gastric surgery and she submitted to a gastro-enterostomy. But the pain remained. Nothing daunted she went to one whom I may describe as a general surgeon. He opened the abdomen but said that he felt so much which wanted rectifying that he closed it again without doing anything. She has now been restored to good health by a little more moral influence, and the sound knowledge of the nature of her doctor.

No man can become a good surgeon unless he is first a good physician. That saying is as true to day as when Sir William MacEwen first spoke it, and special knowledge and technique must always be subservient to the wisdom which can only be acquired by a wide study of human—yes, and animal—life. A man may be a perfect surgical artist, but never a great surgeon, unless he learns that even the most perfect technique is no excuse for bad judgement and lack of wisdom.

OPERATIONS OR SUCCESS?

At the risk of becoming unpopular amongst my younger brethren, I am going to say that I am afraid that we are producing a generation of operators, and not surgeons. With the advent of perfect asepsis the respect for operative intervention has almost ceased to exist. Moreover it has become the fashion to advocate the adoption of more and more radical procedures, in place of those which have given excellent results in the past. It is no longer sufficient to remove a patient's gall stones—his gall bladder must be removed as well. Gastro-enterostomy is being condemned as insufficient for simple gastric ulcer. A partial gastrectomy is now the operation of choice. If I remember rightly, this operation was first urged upon the ground that cancer is so often gift upon long standing simple ulcer, and I believe the risk of malignant incidence was placed at something more than 50 per cent. I have been at some pains to try to find a definite reason for this alarming statement, because I know that the occurrence of cancer after gastro-enterostomy for supposed simple ulcer is quite a rare event. Either the ulcers are only rarely malignant, therefore, or else gastro-enterostomy cures cancer. Latterly, however, the advocates of the more radical treatment have shifted their ground, and it is now stated that my lesser procedure than gastrectomy fails to cure. I suppose my experience of gastro-enterostomy may be regarded as small, because I have not to perform my thousands of operations. Nevertheless, I can lay claim to some hundreds. Perhaps I have been especially favoured by fortune, but I do know that gastro-enterostomy for simple ulcer has been very successful in my hands so much so that I could not possibly advocate the removal of half the stomach on account of a hypothetical risk of subsequent development of malignant disease. The same argument applies to cholecystectomy rather than cholecystotomy. I have performed some hundreds of the latter, but I cannot trace any case in which cancer developed subsequently, and I know from long observation that the risk of recurrence of gall stones is practically non-existent, so long as the cholecystotomy has been adequately performed. It has also been urged that total rather than subtotal hysterectomy should be practised for uterine fibroid, in order to prevent the possibility of the subsequent development of cancer in the cervix if it is left

behind. I recently inquired into the after-history of 250 cases of subtotal hysterectomy, but failed to find a single case of this unfortunate development. Incidentally, however, I learnt of a case of cancer in the vagina, which was said to have developed in the scar following a total hysterectomy. I commend that to all ardent advocates of extreme radical measures.

THE STRAM-HAMMER AND THE NUT

When I was a very small boy I was taken to a great exhibition in the Old Cloth Hall in Leeds. It was not long after Nasmyth had invented the steam-hammer and I still remember watching a man regulating a model of that wonderful invention. He was cricking Breckon nuts with it! I was too young at that time to appreciate the wonderful scientific accuracy of the machine, but I do remember thinking that I could crush them equally well with my teeth.

What is the real reason for this modern desire to adopt extreme measures? It is the love of something new, the love of a great idea, and—yes, I am afraid that I must also add—the ambition for the notoriety of specialism. Specialism is the lay public conceives it—a marvellous gift which enables a man to do something bigger, and incidentally more expensive, than his neighbour. The aseptic principle is a priceless asset in modern surgery, but I would ask you seriously to consider whether the modern ritual is not being overdone. It is not easy to draw the line between reasonable and extravagant methods, but such there is much in the surgical practice of to-day which is purely theatrical. Moreover, our concentration upon technique is deadening our sense of the supreme importance of cultivating clinical wisdom and judgement, the shrewd estimate of the vital capacity of our patient, and the great principle that we should never forget that the greatest artist is he who does the least possible to secure the desired end.

THE ART OF SURGERY

The art of painting and the art of surgery are very similar. There are artists who produce pictures by a few bold strokes of the brush or pencil. Their work captures the imagination and it lives. There is also the artist who produces a picture full of minute detail. It is very beautiful and perfect, but before long it begins to pall, and sooner or later it ceases to attract. So is it with the art of surgery. The surgeon who can grasp essentials, and who is gifted with "vision," because he has viewed Nature from a broad standpoint, lives in the memory of future generations. His work remains because he has studied the great essentials of life. The other obtains a passing notoriety on account of his perfect technique. It is all very pretty, and attracts the eye for the moment, but it lacks that sterling quality which marks real genius. Genius is not a heaven-sent gift. It is the infinite capacity for work—a capacity for using our brains in the study of everything which enters into our existence.

If I may make an appeal to the embryo surgeons of to-day, I would beg them not to be narrow in their ambitions. I would ask them not to be counting up the worldly wealth that specialism may bring, but remember that the passing of an examination, however high its standard may be, and a year or two of special experience will never relieve greatness. Theatrical display of elaborate technique, and the noisy advertisement of the latest methods, will obtain notoriety, but chain them to a life of comparatively joyless work. I would tell them that while it is a great thing to be able to do something better than anyone else, it is a much greater thing to be known as a great scientific worker, who can bring to bear upon his special craft a knowledge of human nature and all those attributes which make men truly great. I would ask them to realize that if they work for the love of working, in the first place, to work for the advancement of knowledge and the universal benefit of mankind they will obtain a great recognition and an ultimate worldly success. I would commend to them the words of Thoreau when he says: "If a man advances confidently in the direction of his dreams, and endeavours to live the life which he has imagined, he will meet with a success unexpected in common hours."

A MEMORY OF ST GEORGE'S DAY

As I came to you across the sea, little more than half-way I recollected that it was the eve of St George's Day—St George, the patron saint of England—and my mind went back ten years to that twenty-second day of April in the year 1915, when Falkenhayn, the German commander, launched on the battlefields of France, before Ypres, his first poison gas attack—that abomination which violated all moral codes, and to which our enemy resorted in order to break our line by torture when he could not break it by overcoming our courage. Ypres, the gateway to the northern coast of France, was in due danger of falling before the enemy. Great Britain was threatened with starvation, the British Empire with ruin and the whole world with catastrophe. When England was in such desperate straits, when the best French division of seasoned Africans, which formed part of the fighting line, broke and retreated in torture and terror, who was it who stood fast and held the enemy back for nearly two whole days under the most appalling conditions ever experienced by any fighting force? It was the First Division of Canadian Volunteers, consisting of the Second Brigade under Brigadier Currie and the Third Brigade under Brigadier Turner. Can the old country ever forget the debt she owes to those men, or to those under General Alderson? Can we possibly forget such individual heroes as Major Knipfpatrick, who led the Fighting Tenth of Toronto, or Captain Straight, who by his courage and self-sacrifice inspired heroes to still greater efforts? In the story as written by Edward Wright we read:

'For a whole week the Canadians held the line that saved the Empire! When the main British relief came up at last by forced marches and went through the German barrage to take over the Canadian position there were scarcely more than two thousand Canadians remaining out of the old division of twelve thousand strong! The British cheered themselves hoarse as they gripped the hands of those newly made veterans whenever they got in touch with them. Canadians! Canadians! That was the British greeting when the weary, staggering, ragged two thousand went back through the German barrage to their rest billets!'

Another writer says

England has a thousand years of heroes before her eyes and she thinks of them with pride. Canada has made her great tradition suddenly! Canada has become a great nation great in territory, great in the boundless wealth of her cornfields, she only needed one thing—the glow of a great tradition.

Now I quote again from your Canadian poet, Robert Service, some lines from "The Younger Son," written before the war:

If you leave the gloom of London and you seek a distant land
Where all except the flag is strange and new
There's a bronzed and stalwart fellow who will grip you by the hand

And greet you with a welcome warm and true
For he's your younger brother, the one you sent away
Because there wasn't room for him at home
And now he's quite contented and he's glad he didn't stay
And he's building Britain's greatness o'er the foam

You will find him toiling, toiling in the north and in the west
A child of nature, fearless, frank and free
And the warmest heart that beats for you is beating in his breast

And he sends you loyal greetings o'er the sea

Then with the voice of the prophet he loses his poem with the lines

You've a brother in the army and another in the Church
One of you is a diplomatic swell

You've had the pick of everything and left him in the lurch
And yet I think he's doing very well

I'm sure his life is happy and he doesn't envy yours

I know he loves the land his pluck has won

And I fancy in the years unborn while England's fame endures
She will come to bless with pride—THE YOUNGER SON!

Gentlemen, we have come to bless with pride the Younger Son. Canada has now a great tradition. The men of Canada, the brave men of Canada, who went out into the great spaces of the earth and made them fruitful, crossed the sea to us in our hour of need and brought with them to Europe that priceless thing which lifts men to the height of heroes, and brings them very near to God. Once, at least in the great war you saved the British Empire and its Allies, and you are bound to us for ever with bonds of gratitude and affection.

SOME MEDICAL ASPECTS OF HOLIDAYS*

BY

SIR HUMPHRY ROLLESTON, BART, K C B, M D, Hon D Sc Oxon,
D C L, LL D,

REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON

The Need of a Holiday

THOUGH bank holidays are comparatively modern inventions, dating from Lord Aberg's Act of 1871, holidays and saints' days are very ancient institutions, so that in Plantagenet and Tudor times the routine of labour was probably more interrupted than in the nineteenth century. But the prolonged summer holiday has now become a much more established article of faith than it was fifty or sixty years ago—long after railways made travelling comparatively easy. Many causes for this change of custom have been suggested, such as mere fashion and imitation, the increased rate and stress of living, of which each successive generation rather boastfully grumbles, and, of course, the explanation, beloved of the *laudator temporis acti*, that the present race has become degenerate and less hardy than its predecessors.

In an interesting paper in the second volume (1924) of *Reports of the St Andrews Institute for Clinical Research*, Professor P T Herring explains "the Law of Fluctuation"—namely, that the constituent units of the body tissues are constantly varying between the two conditions of complete activity and complete rest, and that this mechanism prevents undue fatigue and its bad effects—this law being a necessary sequel to that of Keith Lucas's "all or nothing" response of nerve and muscle. Further, the graded response of a muscle as a whole is due to varying numbers of its units taking part in the response. What is true of the part is, *mutatis mutandis*, true of the whole, and the new law of fluctuation expresses in physiological terms the old ideas of rhythm and alternating phases of activity and repose. The momentary systoles and diastoles of the heart, the diurnal periods of wakefulness and sleep, and the annual holiday are illustrations of the same sequence. But just as the "all or nothing" law applies to units, so do the cardiac relaxations and the night's rest concern the shorter periods of man's life. The taking of holidays or relatively prolonged periods of cessation from work is on rather a different plane and is not of universal application, for those who do no work obviously cannot, by definition, have a holiday; work and holidays are the natural complements of each other, and there should not be any workers without their holidays, it has indeed, been said that overwork is no more meritorious than overeating or any other form of excess.

It would be interesting to attempt an estimate of the value of a reasonable yearly holiday in terms of health and longevity, by comparing those who have worked hard and taken an annual holiday with those who have toiled without a real break. General impression would unhesitatingly lead to the conclusion that constant work without a proper respite for repair must favour early senility. But in marshalling the evidence from individual examples of these two classes of workers other factors must be taken into account, long and healthy life depends to a great extent on a wise selection of parents for hereditary may counteract many sins against the laws of physiological righteousness; thus, as regards longevity, the average duration of life in one of a number of persons, both of whose parents reached the age of 80, was twenty years higher than in another series in which the parents died under 60 years of age (vide Raymond Pearl), a regular holiday may not be adopted until a warning of ill health or a nervous breakdown has made precautions imperative, and a complete life-history, especially the incidence of infectious diseases, must be available. Examples of teachers, colleagues, or others who have ordered their lives on one or other of these lines will no doubt occur to you, so I shall mention two examples only of former leaders of our profession. Sir James Paget

(1814-1899) did without a real holiday for fifteen years (1845-1860) during his hard struggle as a young surgeon-pathologist, this, of course, was long before he "learned the misery of making only £4,000 a year" (eventually he earned £10,000 for some years). He had pneumonia six times between 1851 and 1870, a severe illness from post-mortem infection in 1871, at the close of his long life became, as his philosophically recorded, less and less able to do what he would, and died with "signs of congestion of the lungs." He had the advantage of a long-lived family behind him. Sir Henry Holland (1788-1873), whose span of life was the same, early determined never to allow his income from practice to exceed £5,000 a year, and to spend two months every year in travel, this he did for nearly sixty years (1814-1873), and, like Sir Thomas Browne, died on his birthday, two days after attending the trial of Marshal Bazaine in Paris, being ill for three days in all.

It must sometimes happen that a holiday is unconsciously taken just in time to prevent a breakdown or the onset of an infection such as tuberculosis, and it would be interesting to speculate on the frequency of aborted disease. The lowered resistance which was just about to allow infection to occur is braced up by the good conditions, and infection either does not make a start, or, if it has already taken root, is nipped in the bud or becomes latent.

While fully endorsing the physical and psychical need for a holiday in others, some seniors must admit that they have lost the keen zest of their earlier days to be off for a complete change, and that they no longer count the days before its advent with the same pleasant anticipation as in the past. Age has added inertia, a clinging to the home comforts, and a dislike to face the ills they know not of in unfamiliar surroundings. They no longer have the desire

"To burst all links of habit—there to wander far away
On from island unto island at the gateways of the day"

Such men may no doubt plead that their lives are not like those of most other medical men, not confined to monotonous routine, but varied by different forms of mental activity and their professional occupations diversified by official and public duties. In fact, like some contributors to *Who's Who*, they would subscribe "Work" as their recreation. There may be much argument in this contention from the mental point of view, but it does not provide for hygienic repair and fortification.

Some people never take a holiday and yet seem to get on well. A medical man told me that for twenty years he had never left London, except for professional reasons, and that by walking five or more miles every day he kept in good health, and I know another member of our profession whose experience is the same after ten years. These are, of course, exceptions, and their example is not without danger for the rank and file. Years ago a physician whom I found ill in town in August quoted Sir James Paget's record as a reason for his own self-denial, it certainly seemed that his early death from pneumonia, a few years later, may have been due to lowered vitality induced by following too closely in the footsteps of the great. Comparison between those who "live" and take holidays, sometimes spent at spas undergoing "cures" on the one hand, and those who take exercise but no holidays, though otherwise obeying the dictates they preach, on the other hand, might show but little difference on the whole, and so account for the apparent success of the medical man who never left London for twenty years.

The physical requirements at different ages of life deserve some attention, the young especially when rapidly growing, need much more rest and holidays than is perhaps generally recognized, and certainly more than adults, this is a point which the harassed parent of a large family does

not in any gratefully acknowledge. It is, however, hard to find any physiological reason for the discrepancy between the length of the terms at Oxford and Cambridge and those of students in the medical schools of London. As age advances and habits gain a firmer hold, the demand for holidays becomes less obvious or at least less clamorous. But perhaps the best test as to the suitability of a holiday to the various ages is the simple therapeutic one, so to speak, and to conclude that as long as a person really enjoys a holiday, he or she is of the right age for that form of holiday.

The time of year for a holiday is for many of us largely determined by the general lull which accompanies the absence of others during August and September; it is true that the younger generation, who act as substitutes and pickers up of the rather elusive crumbs left by the absentees, go away earlier or later. But otherwise a holiday at unaccustomed times may be considered to favour of mild eccentricity or impaired health, neither of which is a recommendation or advertisement of solid worth. From the hygienic point of view there is much in favour of splitting up the annual holiday allowance into two or three parts, but each of these should be a complete holiday. Some people are slow starters and take about two weeks to get into the holiday frame of mind and body, and therefore need a more generous reaction than others.

There are the two alternatives (1) of returning year after year to the same favourite spot, which has become a second home with well proved sources of pleasure and satisfaction, and (2) of going to a new place every year so as to expand our limited knowledge of the world and to avoid the disappointment from less favourable circumstances than on the previous occasion. On general grounds it would appear that the plan of a fresh place each year is more suitable for the young and energetic, who are more able to find manifold outlets for their bursting vigour, and that those approaching "the sear, the yellow leaf" will be happier in the haven that they know suits them.

The length of a holiday, like its nature, varies with the individual, although six to eight weeks is the ideal; it may be suggested that just as the necessary hours of sleep show considerable variation, so do the holiday requirements of different individuals. Holidays may be divided into several categories, such as the complete, the partial, the educational, the therapeutic, and the failures. The conception of holidays includes two rather different aspects, which, however, overlap—first, that of recreation, and secondly, that of rest and repair.

1 Recreation consists in change, distraction, and activity of a pleasant nature in a direction other than that of ordinary routine life. It is mainly a psychological remedy, as shown by the good effect of switching off from one line of work to another, thus relieving one part of the mind while healthily exercising another, and possibly, though here we are on rather uncertain ground, exerting a beneficial influence on the corresponding areas of the subconscious. As Sir James Paget¹ pointed out, there is a remarkable contrast between man and other animals in the matter of recreation—for except in the case of young animals, man alone refreshes himself by seeking fresh forms of activity.

The methods of recreation are various: it may be intellectual or physical, indoor or outdoor, and must vary with the individual's temperament and tastes. Although recreation essentially produces a mental rather than a physical change, it may be effected by physical means; thus it is perhaps most rapidly attained by fast or active motion—for example, running, riding, motoring, or flying, though the last is a more or less intelligent anticipation of what will probably hold good for the future, walking, which, at any rate in streets, does not exclude the companionship of black cabs, is therefore far inferior to bicycling or lawn tennis. As a complete change from the strain of life, medical men not uncommonly seek a holiday in stinking, shooting, or fishing, while others, tired of percussing the chest, obtain relief in driving golf balls over or even into bunkers. "A doctor's holiday" was the subject of the late Dr. W. M. Ord's oration to the Medical Society of London in 1884, in which, while admitting a

diversity of tastes, he inclined, apparently from his own hobbies, to the distractions provided by natural history or literature. But though it would be attractive to formulate the most suitable forms of distraction for the various professions and vocations, it is probably wiser to be content with the conclusion that it should be so different from ordinary life that the individual forgets his occupation and habits in becoming a natural man. A sedentary worker's recreation should be muscular exercise in which the mental processes, though no longer the sole form of activity, are in quite a different line, exercise is therefore a specially valuable form of recreation, as it influences both the body and the mind. In a rather analogous sense reading or writing as a form of recreation for the manual worker, while altering the mental outlook, also provides bodily rest, but it should be noted that the total physical benefit must vary according as an open air worker rests in clean air or in a contaminated atmosphere, such as that of a cinema or concert hall, or, again, according as a worker in a badly ventilated workshop takes his time off in a garden or in a stuffy room. On the other hand, an intellectual worker who seeks recreation in bridge or the theatre is thus benefiting his mind without any accompanying physical advantage. An important factor in recreation is the faculty of keeping thought-tight compartments in the mind whereby attention can at once and completely be switched off from one subject to another—a faculty said to have been possessed by Gladstone and Kitchener. Recreation is of course fully recognized in the ordinary working life of everyone, and the degree to which it is put into practice no doubt has a bearing on the need for a prolonged holiday; some maniaacs have more will than recreation, and vice versa, and, other things being equal, the need for prolonged holiday will vary directly.

2 The factor of rest and repair is part of the rhythm of life—as shown in the frequent distoles of the heart and the night's sleep, but a holiday differs from these in being at much longer and often irregular intervals, and in being under the control of the individual's discretion or indiscretion. What should be, but is not invariably, a form of holiday occurring at short and regular intervals—one day in seven days holiday—is the weekly Sabbath ordained in the Scriptures which has been expanded into the modern week-end habit, thus enabling the conscientious week-ender to obtain 104 days of freedom during the 365 days or the year. A well arranged week-end habit may thus to some extent obviate a prolonged holiday of six to eight weeks in the year, in the now far-off eighties a friend of mine, who was often chided on account of his rather frequent disappearance from the hospital where he was house surgeon, retorted "It is all very fine for you to laugh at me, but I keep fit, whereas you get knocked up and then have to be away for two or three weeks." But the week-end is more often a diversion or distraction than a rest, and sometimes, though a change, is not devoid of fatigue. It is perhaps only a natural outcome of the cry of "the wear and tear of modern life" that the *Daily Mail* some years ago made the suggestion that if one day a week were spent in bed, the medical profession would have much less to do than is at present necessary. A few people indeed begin the regular summer holiday by going to bed for a week, but usually these are neurosisthenics and are or think that they are, on the verge of a breakdown when the date of their annual holiday comes round.

The rest factor in a holiday, ordinarily so called, nearly always concerns mental rather than physical activity—in fact increased exercise is usually recognized as an essential feature of holidays. An important point is to secure complete change of environment and mental atmosphere, to get away from him- or herself, to pass a sponge over the mental slate and so wash off the dust and irritants of ordinary existence; for this reason a holiday at home has distinct drawbacks. As a first step it may be necessary to have a cessation of activity before passing from one state of life to another however different, but this again had better, because more easily, be taken away from rather than at home.

In order to secure a more complete change of mental atmosphere there is much to be said for a holiday apart

from the family or usual associates, at any rate in the case of some persons. Sir Henry Holland, who probably got the most possible out of his long life, though he was not an epoch-making pioneer in medical science, went abroad alone yearly for two months during fifty years, and depended for social intercourse on chance meetings on his journey. Respite from soul-destroying routine and worry should be continuous and complete during the holiday, but often men who obey the call for fresh air, change of scene, and exercise, keep in touch with their profession or business while staying in this country. Again, men who live most of the year in town for the sake of their work may take a house in the country for the holiday months of August and September, and come to town once or twice a week to keep an eye on their work, they thus slack off but do not leave off their usual routine, while getting more into the fresh air, but they do not get an entirely new mental atmosphere—they change their physical but not their psychical environment, in fact, such a holiday is partial instead of being complete, it is more like a glorified and oft-repeated week-end and approaches the life of a stockbroker who lives at Brighton and comes up to Change so many days a week. The physical health may benefit, but the mental groove is still between the same lines. There is therefore an advantage in taking holidays abroad, where calls, consultations, and certificates are not so likely to reach their intended recipient and as a rule correspondents cease from troubling. Much wisdom lurks in the interesting announcement in the social columns of the press that "Mr. and Mrs. Chamber-Brown have gone abroad, and letters will not be forwarded." Foreign travel also involves a more complete change of scene and of mental attitude, whereby the individual loses sight of self among the innumerable new objects of interest, in spite of Horace's dictum, "Coelum non animus mutant qui trans mare eurrunt." A sea voyage has similar advantages, and further secures more isolation, which, however, is now not quite so complete as in the pre wireless days. In addition it has the virtue of enforcing rest, which may not be an accompaniment of foreign travel and the itch to see as many capitals, pictures, views, and sights in the least possible time. Such a Continental scramble may, indeed, leave the traveller with an indigestion of impressions and ideas, and more fatigued in body than when he started out, so that he really requires a lotus-eater's rest on his home coming. A holiday abroad has, of course, a wide application as an education, and its value may be augmented by careful preparation in acquiring a knowledge of the country, its history and its language, it thus forms what might be classified as the educational holiday.

The Educational and Utilitarian Holiday

While the health-bringing influence of a holiday depends on fresh air, sun, and change of environment, the good effects on the mind are due to occupation in new directions—such as natural history, science, literature, art, and archaeology. A holiday may therefore promote general culture and broader interests, and thus initiate a hobby, and so prove a valuable asset by providing recreation for the remainder of the year. This, indeed, is particularly true with regard to holidays spent abroad, with a foreign language, scenery, architecture, and manners to stimulate the visitor. Reference may be made to the question whether, as medical men, we should, when passing through great medical centres, be better advised to avoid a return, even for a short space to a professional atmosphere, or whether we should be wise to take an opportunity of widening our knowledge and sympathies by visiting the medical school and seeing the buildings, laboratories, libraries, clinics, hospital facilities, and the prominent professors and teachers. Acquaintance thus made with places, personalities, and ideas will help to correct the all too common tendency to insularity and a narrow outlook which unconsciously grows and gains on us with the passing years. Though to do so is certainly open to the condemnation of its resemblance to a business man's holiday, there is a distinct difference between a flying visit to a medical school while happening to pass through a large town and on the other hand, going abroad to do a definite piece of work.

Does not the benefit obtained from such an incidental visit more than counterbalance any drawbacks due to its shabby character? Medical congresses abroad may be regarded as in much the same category as the passing visit to a medical centre, for though professional in name the general atmosphere is in reality much of the holiday picnic, they are a means of obtaining a welcome change of surroundings and combining a medium of work with pleasant travel and the opportunity of making fresh friends.

Holiday Failures

Indian natives who have failed for but not succeeded in obtaining a B.A. degree sometimes advertise themselves as "failed B.A.s," and in like manner there are holidays that fail, though they are not correspondingly a matter for boasting. A man may go away to the seaside and uncomfortable lodgings to be cramped up with his family, whose healthy noise and motousness—especially when, as in some Augusts, "the moon is in the sky every day"—gets on his nerves the whole time, and from which he has no excuse, such as his work or real diversion, to justify his escape. In this plight a man may count the days to his release from the discomforts and boredom of a so-called holiday. A holiday without his family is sometimes the best for a man of the irritable genius type. As regards physical health, the conditions at home may be superior or inferior to those encountered on a holiday, especially abroad, and the adverse conditions when away may be little more than counteracted by the increased amount of time spent in the open air and healthy exercise.

The most serious failure is that of the perpetual holiday often anticipated vaguely without any thought, much less realization, of its actual contingencies throughout a strenuous career, a successful business man retires or a professional man is placed on the shelf by the age limit, and what does he find? Unless blessed with wide interests or mercifully aimed with some engrossing hobbies, the long-expected fruit of delight may turn to ashes on his lips, and he experiences what Bernard Shaw calls "the horror of the perpetual holiday," he will then itch for real work, and even go so far as to return in a subordinate position in his own business, or, if no deliverance in the form of public work comes to the rescue, proceeds to deteriorate both in body and mind.

An aspect of holidays that should be mentioned with due circumspection is the effect on some members of the family of the holidays of other members. In probably not very rare instances parents suffer from the strain entailed by the holidays and proper entertainment of their children, a quiet, orderly household, with plenty of elbow room for those of mature years, suddenly becomes crowded with exuberant youth, full of restless energy and not unaccompanied by audible signs of exuberant enjoyment or excessive expostulation. The middle-aged, already "set" in their habits and somewhat intolerant of noise, often find it hard, though it is undoubtedly salutary, to become young, and when there are extraneous sources of anxiety may abandon any such attempt and be left with nerves jangled and irritable.

Diseases due to Holidays

Although a thorough change is an essential part of a complete holiday, there are possible abuses in the method of making this change, and from the practical, not from the cynical, point of view, a few remarks may be devoted to 'the diseases due to holidays.' They may be divided into (1) those occurring during absence from home, and definitely due to the unusual conditions and manner of life, (2) those arising after the holiday, but traceable to its conditions or influence.

1. It is unnecessary to discuss constipation due to interrupted habits caused by the exigencies of travel, food poisoning resulting from experiments in unaccustomed articles of diet, water-borne diseases, such as enteric fever, or other endemic infections, such as malaria and Malta fever, except to intimate that due precautions should be taken with regard to diet and the choice of the foreign resort and to local conditions at the time of the visit, such as the endemic prevalence of influenza, of enteric fever—

which obviously suggests T A B vaccination before leaving home—the presence of mosquitos and of endemic malaria. Just as I was revising this paper I came on an article by V Y in the *New Statesman* (1925, vol. 529) entitled "DANGER!" and beginning, "Holidays are for the robust," and humorously exaggerating the risks. Accidents such as sprains do not need any reference, but the risk of cardiovascular strain must not be forgotten. Thus a middle-aged man after ten months or more of sedentary life suddenly, without any training, launches out into active exercise such as he was accustomed to take thirty years ago, for example, he at once starts climbing in the Alps, and may come seriously to grief by dilating his heart. Unwanted sea-bathing and swimming may prove too much for a man whose heart and arteries have insidiously undergone the changes of arteriosclerosis. Some of the bathing fatalities ascribed to cramp may really be angina pectoris.

2. *Diseases arising after the Holiday but traceable to its influence*—A drawback to travelling, especially for long distances abroad, is the risk of picking up infection—flu, influenza, catarrhal, or tonsillar—from railway carriages and sleeping cars. It is disappointing after an invigorating holiday, such as at a Swiss winter resort, to develop a cold or sore throat directly after return, and thus to realize that much of at least the physical benefit of the change has been neutralized. This is therefore an argument for motoring abroad, provided the weather is suitable, in preference to railway trains.

Another occasional sequence to a holiday is that the acquired immunity, due to unconscious intermittent vaccination with the micro-organisms of dirt, catarrhis, lapses in the pure air of a holiday, and that a cold or sore throat asserts its right to afflict the holiday-maker so soon after his return that the sunburn on his face has not as yet vanished, if the explanation of the lapse of acquired immunity is correct, it would be natural to expect that a long holiday would be more likely than a short one to be followed by this mishap. It has been thought that those engaged in post-nortem work are more prone after a holiday than at other times to become infected and suffer from boils or sores. Sir James Paget held this view, and in writing on a surgeon's freedom from infection while daily exposed to pus and his susceptibility when no longer thus protected, quotes E. Symes Thompson's experience that while engaged in doing necropsies he escaped infection, but on returning from a holiday to this work a scratch on his finger was followed by severe illness.

Advice to Patients

Where, when, and how to take a holiday to the best advantage is a subject on which most people feel that, as on a number of other subjects, they are authorities, and are more inclined to impart than to follow advice. Though medical help is commonly sought as to the best place to undergo a cure for some morbid condition or tendency, and a holiday or rest from their labours is often prescribed by medical practitioners as an essential of treatment, ordinary persons seldom take expert opinion about their holidays, except from travelling agencies. The healthy boy or young man regards a holiday as merely a return to a state of freedom from the toil and the restrictions of civilized and artificial life, and would consider it absurd to dream of taking advice or of making any special preparations for a return to a state of natural and simple existence. But however it may be with them, their elders would often gain by adopting the humble course of asking advice.

National health is attracting ever-increasing attention, and many improved methods have been instituted among the directions in which a useful advance might possibly be made is the more careful choice and arrangements for holiday-making. Those seeking advice should be impressed with the really serious importance of selecting the right kind of holiday and place, and further with the need for self-education in arriving at a proper decision. Just like any other course of action in life, a satisfactory holiday demands some trouble, though it might be urged that some of those who are in the position of advisers in this matter are themselves cranks and should practise in conformity with their preaching. The ordinary healthy person leaves the selection

of the place of his yearly holiday largely to chance, whereas skilled medical advice might effect a good deal in obviating failure in holidays. A sedentary worker often suddenly starts on active exercise at the very beginning of the holiday without any preparation in the way of training the heart and muscles for the increased strain thrown upon them. In the young there is so much reserve power that real harm seldom results from such rapid transition from solely intellectual to mainly physical activity, though not uncommonly after a holiday full of unwonted exertion there is on returning to work a feeling of lowness and fatigue which takes a week or so to wear off. It need hardly be mentioned that after an infection, such as influenza, a young patient must be cautioned against starting active exercise with too much enthusiasm, on account of the risk of myocardial strain. But as the years glide by and middle age becomes established, the margin of reserve narrows, and the holiday-maker is surprised to find himself suddenly pulled up by cardiac pain or distress on returning to the athletic habits of his youth. The risk of such an unpleasant experience should certainly be minimized by advice based on a medical stocktaking directed to consideration of the state of the blood pressure, heart, and arteries. A holiday should not be regarded in the light of an incident, such as an evening party, which can be embarked on without some measures of preparation, some time before setting off for a climbing expedition in Switzerland or stalling in Scotland, a course of walking, hopping, skipping, or training for the muscular and cardiovascular systems should be undertaken. Further, the week-ends might be utilized as trial trips. By such a course of training the risks of sudden strain should be eliminated. Patients with anaemia should be cautioned against taking much exercise, for clinically the importance of rest in bed for patients with grave anaemia is well recognized, and experimentally G. O. Brown found that after a long period of sedentary existence in cages, in which presumably little blood was being destroyed and made, dogs then exercised vigorously for several days showed temporarily a great decrease in the circulating haemoglobin and red blood corpuscles from increased mechanical haemolysis, the compensatory function of the bone marrow being caught napping. In dogs previously exercised, as in human athletes during training, no such anaemia results, and the general experience is that after short periods of exercise the haemoglobin and the red count are raised. In recommending a holiday to another attention must be directed to the physical condition and power, temperament, inclinations, and hobbies, and for successful advice personal knowledge of the individual and of place counts for much, for in unaccustomed holiday would be worse than useless. The worries attendant on a long journey, with the rush of getting off and the care of children and luggage, may be minimized if the anxious mother and the irritable father take a sedative dose of bromide to render them philosophic, cheerful, and less prone to a train headache.

Holidays are often taken at spas, and here the physical benefit which results, or should result, from the "cures" for some bodily disease or disorder, may be impeded or modified by the boredom and dislike of the place chosen by high authority for his victim. Therefore, in considering the course of action, the mental as well as the physical factors should be taken into account. The experienced knowledge of practitioners who, like the late Sir Hermann Weber, specialize in hyrology, climatology, and balneology, is a valuable supplement to the particular knowledge of the individual possessed by his medical attendant. A dance of over-fatigue and of overfeeding, which the stimulating air and interest may excite, should be insisted upon.

A Lecture

ON

THE PSYCHOLOGY OF ANIMALS SWALLOWED ALIVE.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND ON JUNE 5TH

BY

SIR JOHN BLAND SUTTON, Bt.,

PRESIDENT

Many discoveries and observations made by naturalists are of little interest to the public but animal psychology and vagaries of the human mind are interesting to all

When sitting in quiet contemplation digesting after dinner, with beneficent microbes hard at work within me, I sometimes wonder if animals who swallow their prey alive are worried by the aerobiotic efforts of victims trying to escape

The same idea must have occurred to many boys after reading the curious experience of Jonah, swallowed alive by a big fish and subsequently vomited upon the shore for his adventure. In Matthew's Gospel the creature that swallowed Jonah is called a whale. Matthew may have

been a good evangelist but not a naturalist. This is not surprising, for he was a customs officer under Herod the Tetrarch. There is a tradition that Jonah was the son of the widow of Zephath, Eliah restored him to life, and delivered him to his mother, saying, See, thy son liveth.

The story of Jonah and the whale has been the source of many quips. There is a misericorde in the stalls of Ripon Cathedral representing the prophet in the act of being swallowed by a whale—the mouth of the beast is well furnished with teeth—and another representing him emerging from the mouth of the whale (Fig 1). The verger supplies this pun. When Jonah felt himself in the power of the whale, he was down in the mouth and felt he was going to blubber!

The open mouth of a big whale may measure 20 ft in length, 15 ft in height, and 9 ft in width. Such a chamber would easily accommodate twenty Jonahs standing upright.

Many believe that the story of Jonah and the whale stands by itself, but the *Boston Post Boy*, October 14th, 1771, reports upon undoubted authority that an Edgartown whaling vessel, after striking a whale, had one of her boats bitten in two by the whale, and Marshall Jenkins, one of the crew, had been taken into the mouth of the whale, which had then smelt with him. On returning to the surface, the whale had ejected him on to the wreckage of the broken boat, much bruised but not seriously injured. The whale concerned in this exploit must have been a big sperm whale.

In old pictures representing the Jonah Miraculous the creature which swallowed the prophet is usually a whale with teeth, but among the beautiful stained glass windows in the Church of St John at Gouda there is one in which Jonah is shown full and immaculately clothed, walking out of the mouth of a huge cod-fish.

Sharks

Sharks are well known as formidable tyrants of the ocean, and their voracity is almost beyond belief, and sometimes ends in their own destruction.

The diodon, a curious fish not uncommon in tropical seas, is furnished with strong teeth which enable it to break off and crunch big pieces of coral on which it feeds, and its skin is beset with sharp spines. This fish has the power of inflating itself until it assumes the shape and size of a big bill, when inflated, the spines stand out like the quills of a porcupine, hence the popular name of the diodon is porcupine fish.

Durbin, in 1832, was on the *Beagle* in the South Atlantic when he became acquainted with this curious fish. On the authority of Dr Allan of Lorient, he states that big sharks swallow the porcupine fish, and has frequently found

it floating alive and distended in the stomach of a shark. On one occasion a porcupine fish swallowed by a shark had eaten its way out not only through the coats of the stomach, but through the walls of the body, and thus destroyed its captor. Darwin asks, Who would ever have imagined that a little soft fish could have destroyed the great and savage shark? The diodon inflates itself with air and water, which it expels with some force when it deflates. The jets of water must cause some curious ticklings to a shark with a lively diodon in its stomach!

No one need be sceptical in regard to a shark's ability to swallow a porcupine fish, or of difficulty in accommodating the fish when it reaches the stomach. Some idea of the gastric capacity of a shark may be gathered from the following evidence. Sir William Turner dissected a Greenland shark (*Lacnæus borealis*) nearly 12 ft long. Its voraciousness was revealed by the contents of the stomach: one cod fish and two salmon averaging 3 ft in length, nine haddock, a small skate, the carcass of a small porpoise without its head, and bits of blubber.

A remarkable example of the voracity of the tiger shark was reported by F. A. Mitchell-Hedges. A party of explorers, engaged in deep sea research in the Caribbean Sea, killed one of these ocean tyrants. This shark measured 17 ft in length, 9 ft in circumference, and weighed nearly 2,000 lb. Its stomach contained eighteen deep sea eel-fishes (21 in length), each weighing between 4 and 5 lb. Every one had been swallowed whole. It seems a vicious taste on the part of the shark to swallow these extraordinary creatures. They resemble animated coal scuttles. The fish in this case is called a tiger shark, not on account of fierceness or

rapacity, but for the mottled appearance of its skin. Lockwood, an American naturalist, studied the habits of king crabs in 1870. In New Jersey they are used for feeding ponies and hogs, female crabs are preferred. A female king crab may contain half a pint of eggs, they are like mustard seed, but of an ash green line. There is a belief that this diet makes poultry lay, fattens

FIG 2—Sperm whale and whalebone whale in outline to show the peculiarities of their heads (F. B. Hart)

fowls and hogs, but gives a shocking flavour to the flesh of both.

Things more curious than fishes are sometimes found in the stomach of a shark. In 1779 Michael Fitton, in charge of the tender of H M S *Iberigenny*, cruising off

FIG. 3.—Showing porcupine fish (a) deflated and (b) inflated. When inflated it is as big as a coco-nut. (Günther)

St Domingo, caught a large shark, which was hoisted on board the tender. Some seamen cut the head off the fish and cleaned the jaws, and others opened its maw, it contained "a parcel of papers tied up with string." The letters were of recent date, and Fitton had them dried on deck and read them. One of the letters related to a brig called the *Nancy*, which had been seized as a prize. The captain and the crew of the *Nancy* were tried and convicted with the aid of this letter in the Old Court House, Kingston. How this packet got into such a curious post-box is a matter for conjecture.

Lat and be eaten is the rule among fishes in the sea. Fishes not only eat each other but even their own off-

FIG. 4.—The black swallower (*Chasmodon nigrum*) a deep sea fish which swallowed a fish larger than itself. Half natural size. (Natural History Museum)

spring, and a few are so ravenous that they attack and swallow fishes bigger than themselves. The black-swallower (*Chasmodon nigrum*) lives at a great depth in the Atlantic Ocean, below 1,000 fathoms. There is an example in the Natural History Museum which was dredged at 1,500 fathoms, and it contains a dead fish bigger than itself (Fig. 4). The captured fish was clearly discernible through the tightly stretched belly when the fish came to hand. The black-swallower is clearly allied to cod-fishes, which are cannibalous, and is sometimes found floating dead on the surface of the ocean with a fish in its stomach. When a fish has been swallowed in such circumstances decompo-

sition outstrips digestion, and the generated gases cause the fish to rise so rapidly from the depths of the ocean that it is killed and floats on the surface. This may be regarded as a good example of post-mortem revenge.

In Ocean Crime

Most of the deep-sea fishes are pale green or blue when caught, but they turn rapidly black. Some are colourless and gelatinous, a few are silvery. In museums they are usually represented by models and these are usually black but their characters are blacker. The example of the

FIG. 5.—*Gigantura roxar* 80 mm. long with a *Chaulichodus* 1-2 mm. long in its stomach (C. T. Pagan) and the head of *Chaulichodus* to show its teeth.

black-swallower has been in a measure eclipsed by an exploit of a deep-sea fish, *Gigantura* (Fig. 5) obtained in the Atlantic by the Dana Expedition (1920-22), and carefully described by Mr. C. Tate Regan. This fish lives at a depth of 500 metres. Its eyes are telescopic closely packed together, and directed forwards. It has a formidable dental armature—the teeth are slender, sharp, and depressible. In each jaw a pair of anterior canines directed forward are followed by a series of strong spaced teeth, with smaller teeth between them. The fish is precocious, and has a very capricious stomach. It is probably a lurking fish that steals upon its prey, aided by powers of vision beyond the ordinary.

In the "Dana" specimen the fish was 80 mm. long but neatly picked in its stomach there was a deep-sea fish, *Chaulichodus*, 140 mm. in length. *Chaulichodus* has a formidable dentition, and the *Gigantura* must have been desperately hungry to attack a fish twice its length and formidably armed with teeth. After an examination of the body of

FIG. 6.—The black fish (*Dallia pretorialis*) a fish found in Alaska its vitality is astonishing. (Turner)

the victim, Regan reconstructs the crime in this way. The *Chaulichodus* was seized by the middle, and was swallowed double until it reached the posterior end of the stomach when its head and tail still protruded from the mouth of its captor. These were then taken in and bent back until the whole fish, now doubly folded, was in the stomach of *Gigantura*. Digestion affected the part first swallowed where the fish has quite disappeared, exposing the vertebral column for a length of 18 mm. It seems horrible to be slowly digested alive!

The pike is the most voracious of freshwater fishes and consumes large quantities of food. Big pike will seize

rats, voles, and it is said they attack foxes and small dogs. They gorge each other occasionally with extreme thoughtlessness for their own safety. In 1880 Dr Burton supplied Buckland with the following story. A boy saw in the Tweed near Kelso what he thought was a fish with a tail at each end of its body. He caught it and was astonished to find two pike, one of which was trying to gorge the other. They were alive, and he put them into a tub of water and parted them. As soon as they were separated the larger pike attempted to gorge the smaller. One weighed 3½ lb, the other 2½ lb (Fig 8).

Fishes are sometimes careful in what they attempt to swallow—probably from experience. A John Doiv, living in an aquarium with some fifteen spined sticklebacks, was foolish enough to swallow one. He swam around squirming as if he had gripes. After two minutes he vomited the spiny little fish, which seemed none the worse for its adventure and went back to the weeds apparently as unconcerned as if he had not been disturbed. Kingfishers are fond of the little fishes known as bull-heads, or miller's thumbs, but they are cautious in selecting their prey, for the big pectoral fins of these fishes may stick in their gullets. This is another form of retaliation. In musing on such events I think most will agree with Shakespeare

The sense of death is most in apprehension,
And the poor beetle that we tread upon,
In corporal sufferance feels a pang
As great as when a giant dies.

A live fish in an animal's stomach must cause some discomfort.

The black-fish (*Dallia pectoralis*, Fig 6), discovered by L. M. Turner, lives in the sphagnum ponds and swamps of Alaska. These fishes exist in enormous numbers and are the chief food of the natives; they are caught in specially made baskets. Between May and December many tons of these fishes are taken to the villages as they are exposed to severe temperatures and cold wind. The mass of fish in each basket is frozen in a few minutes. When required they are chopped out with an axe. The vitality of these fishes is astonishing. They will remain in the grass baskets for weeks and then brought into the house and thawed out. They are quite lively. Dogs swallow them eagerly. The heat of the dogs' stomach thaws the fish, and the movements of the revived fish soon cause the dog

to vomit it alive. The fish seems to be a long-suffering creature. What of the dog? We may say of our friend

—he got rid of an ill-considered meal in a sagacious manner. Several varieties of our freshwater fishes bury themselves in the mud during winter months. This is also true of frogs and toads, but they are not frozen.

In tropical countries some fishes bury themselves in the mud during the dry season. This summer aestivation is well illustrated by the mud fish of Uganda. The mud fish (*Protopterus*) abounds in the marshes around the Victoria Nyanza; it is a curious creature, and breathes by lungs and gills. This fish is eel-like in shape, and may attain a length of six feet. It is rapacious on worms, frogs, crustaceans, and its own kind. The cannibalistic instinct is so great that it is difficult to keep mud fishes in an aquarium, for they eat each other. In the hot season the marshes in which these fish live dry up, to meet this change they burrow into the mud, coil up at the bottom of the burrow, and surround themselves with a capsule of mucus secreted by the skin glands (Fig 7). Sequestered in this way the fish breathe entirely by their lungs, half the year, and remain secluded in the marshes until the return of the rain. When

mud fish adjusts itself to the cocoon, the flask-like cavity which contains it is closed by a perforated lid, the margin of the hole forms a funnel which leads to the lips of the fish. If a straw be gently passed down the funnel it will if alive utter a cry. The fish is so completely encased that it

may be dug up and transported anywhere. The Baganda call the mud fish, some natives regard it as a delicacy and keep it as a provision in elod. Some years ago a mud fish was brought in a elod to the Zoological Gardens, where it was released, and lived and thrived for three years.

Snakes and Frogs

As a rule people dislike snakes, but some snakes are harmless and can be easily tamed and allow themselves to be handled. Some snakes become affectionate in captivity but most are morose. Even a cobra may become a pet as in the case of the albino cobra caught by Mr. J. C. Roberts of Delhi. Albino snakes are rare, and in this instance Mr. Roberts is very

attached to this cobra, carrying it about everywhere with him and allowing it to careen him. The dislike to snakes may be in part due to the influence the

serpent creased over his. The serpent in this instance must have been a tree-snake, because in Milton's description it climbed the apple-tree. It was a snake that

'Led his credulous mother, to the Tree
Of prohibition root of all our woe'

Snakes, especially cobras, are prominent in the Hindu Pantheon. There are many snake tales in Hindu religious writings, and Lama stories in which a prince accidentally swallows a snake which lives on his vitals.

It is impossible to comprehend reptilian psychology, Joan Procter has described a curious instance of a silver tree-snake fixating a lizard (Fig 9). The tongue of this snake is coloured in the same style as its head when the tongue is protruded through the rostral notch, with the lips closed, it appears to be a continuation of the snake's snout. She has seen a lizard watching the hovering tongue in perplexity, quite engrossed, and the snake staring at close range without stirring the usually swift and cautious prey. Miss Procter describes the effect of this "pulling faces" as really most arresting to witness.

It is easy to prove that the prey of constricting snakes are frequently swallowed alive and survive delivery by human agency.

Rudyard Kipling supplied me with the following incident. At Bateman's, in the county of Sussex, the gardener found a grass snake with a bulge in the belly, and promptly lapped off the snake's head, slit open its belly, and with a little help "a frog slid out head first, but alive." Rain was plentifully lubricated with silver, and on the ramp there were rails of two fangs. Otherwise no damage. The frog emitted a low croak as it was returned to a proper home among the lilies in the pond.

John Roscoe, missionary and ethnologist, while travelling from Uganda to Gondokoro, came across a snake engaged in swallowing a big frog. It was curious to watch the frog struggling to make its way down the snake's gullet, evidently thinking thus the way of escape. A native killed the snake. Roscoe opened it and released the frog which sat blinking as though astonished to see the light again, and then jumped among the grass.

Tree-frogs are favourite food of snakes. They have pads on the ends of their fingers and toes. The skin covering the pads contains glands which secrete an adhesive fluid which enables the frog to stick on a slippery surface such as a leaf, they adhere as much by the belly as by their digits. Tree-frogs can jump, when the artist was engaged sketching the frog (Fig 10) he suddenly missed it and began hunting around. In despair he sat down and looked at the drawing. Suddenly he was astonished to hear "Eep, eep, eep," close to his ear, and felt something cold on his neck. To his astonishment the frog was sitting on his shoulder croaking agreeably and—criticizing the drawing!

Gardow, whose interest in amphibians and reptiles leads him to keep and tame frogs and snakes, considers the grass frog "a jolly and intelligent fellow."

We know little, and can only surmise in relation to reptile psychology, but I have heard of a psychologist who made an excellent use of a frog in the following circumstances.

A thin and foolish woman believed she had accidentally swallowed a frog and that her thinness was due to the frog eating the food in her stomach. In order to dispel the illusion the doctor gave the patient an emetic and during the vomiting he slipped a small frog into the basin. When the patient saw the frog her joy was great, but in a few minutes her depression returned. "Oh!" she exclaimed,

"I am sure this frog has left some young creature in my stomach." The doctor looked wise, pulled out his magnifying glass, and after critically examining the frog said unto the patient, "Fear not this frog has not left any froglet inside you. Behold, it is a male!" The patient was quite satisfied, became happy and in a few months was pained again. She was not a naturalist, and therefore ignorant of the fact that it is difficult to tell the sex of frogs by mere inspection except at the breeding season.

Miss Kingsley knew a witch doctor at Kacongo West Africa, who treated bewitched persons, and was successful in removing the witch with rubbings and an emetic. In the vomit he always found several lucky young crocodiles. Magic and mystery worthy of a conjurer!

Snake swallowing Snake

Deglutition in snakes is a remarkable process. These reptiles are carnivorous and as a rule take living prey. Many swallow the victim alive, some kill by constriction. Poisonous snakes kill small mammals, birds, and fishes almost instantaneously and swallow the prey at leisure. The progress of deglutition is often slow and laborious, and can be watched in a menagerie. A python twenty feet long can swallow a goat or a pig. In some countries (Congo Territory) when the natives find a python gorged with a pig they kill the python, release the pig, and then eat both the python and the pig.

In reptile houses the fondness of snakes for frogs is cleverly utilized. The king cobra eats snakes and disdains frogs. In England it is difficult to obtain grass snakes in winter; the keeper gives the grass snake a frog and then passes the frog-containing snake to the king cobra, who thus gets the captive frog as well as the snake. Even snakes can be tamed.

Cannibalism signifies the eating of human flesh by human beings; the term "cannibal" is often applied to animals which eat their own species. It is true that snake swallows snake sometimes accidentally, sometimes intentionally. It occasionally happens in menageries that two snakes fasten on the prey and as neither is willing to let go its hold the stronger will engulf the prey and the snake which clings to it. Thus, in the well known case reported by Brittle, a big box eleven feet in length

fastened on a pigeon, a companion box nine feet in length also fastened on the pigeon. In the course of a night the larger box swallowed the pigeon and the box, and, what is more remarkable, it not only digested them but survived and twenty-eight days later took a pigeon. This was clearly an example of unintentional snake cannibalism.

The king-snakes (*Ophibolus*) common in the United States, Mexico, and Central America, are recognized cannibals. These pretty constricting snakes may attain a length of six feet; they are mild and inoffensive to man, allow themselves to be handled, and learn to recognize their keepers, and feed from their hands.

The king-snake is named from the fact that it is immune to snake poison, this reptile eats birds, lizards, and small mammals but prefers snakes, and even poisonous snakes. It is said that king-snakes will eat eels, probably mistaking them for snakes. They eat their own species. When animals are given them for food they get excited, and when several king-snakes live in the same compartment they are apt to attack and swallow each other. The liability to such accidents is well known, so that when king snakes, living in company, are supplied with frogs and mice, the keeper looks after them, because, if two snakes seize on the same prey,

FIG. 10.—Tree frog (*Hyla blanda*), Procter) showing pads on the tips of the fingers and toes. The first finger slightly longer than the second is used as a thumb in life.

Snake swallowing by snakes was well known to the ancient Egyptians. When Moses and Aaron met the magicians in Pharaoh's court they knew the trick of making serpents become stiff rods, and when cast upon the ground Aaron's rod swallowed up the Egyptians' rods (Exod. vii, 12). Meditations on the psychology of the swallowed suggest that the animal world may be divided into swallowers and the swallowed. A whale swallowed Jonah, but it is wiser for a man to swallow a whale than to swallow a heli

DIFFICULTIES IN THE DIAGNOSIS
BY
G. LOVELL GULLAND, C.M.G., M.D.,
PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, PROFESSOR OF MEDICINE AND CLINICAL MEDICINE IN THE
UNIVERSITY OF EDINBURGH

same state. It has steadily enlarged and the diagnosis is undoubtedly correct. Since my last examination the kidney had increased considerably in size, and so altered in shape that it looked at first as if a splenic enlargement was superadded to that of the kidney. The converse of this case was supplied some time ago by a very uraemic woman with great digestive disturbance, who came to me with the diagnosis of cancer of the stomach. Her left kidney had been removed for pyonephrosis many years before, and the spleen, which was only moderately enlarged, did not come forward as usual, but, in the recumbent position, lay well back in the left flank and under the ribs, and had to be looked for in these cases when they first come under consideration. It is so typical that no error is caused by it.

But even then abnormal cells will thus
which will give the necessary indication, though
sometimes few in number

Radiation may apparently, however, sometimes produce

CHRONIC GRANULAR LEUKAEMIA

In the chronic granular leukaemias the disease is so insidious in onset that the first thing to attract attention, if the patient comes under observation before the anaemia is marked, is usually the enlarged spleen. It is surprising how often there seems to be difficulty in determining whether it is the spleen which is enlarged or some neighbouring organ. I remember a febrile leukaemia in a woman, many years ago, which was sent into a surgical ward as a cellulitis of the abdominal wall. The surgeon was clear that this was a wrong diagnosis, but thought the spleen was a tumour of one of the pelvic organs, and transferred the case to a gynaecologist, who was certain that the tumour was not pelvic, but refused to determine its nature. Of course a blood examination settled the matter. Enlarged spleens in leukaemia may and do wander all over the abdomen, and might be taken for any organ in turn, according to their temporary position. Comparatively small enlargements are often taken for tumours of the splenic flexure, and several times patients have come to me who had been x-rayed after barium meals and enemata. The true nature of the mass was only suspected when the passage was found normal. It often takes more than a momentary examination to settle whether a given enlargement is spleen or kidney. Neither organ, when enlarged, invariably retains its typical shape, the kidney may become very superficial, and the colon which crosses it may be loaded or empty and spastically contracted, and not easily made out, and there are many cases of kidney swelling with blocked ureters in which the urine gives no help. Some cases have required an enemata, intestinal catheterization, full blood examination, etc., before their nature was definitely determined.

To-day I saw a man whose right kidney was removed some years ago for calculi associated with constant pain and haemorrhage and the formation of a large tumour. At operation the kidney was found to be cystic in addition, and it was suspected that the left kidney was in the

a condition closely resembling myelocysthaemia. Some years ago, in November, I saw a lady whose breast had been removed for cancer a year before. She had been treated by x-rays from that time till August. She was anaemic—small ends of both clavicles, the liver was down to the umbilicus and apparently nodular, and the spleen was palpable. Cancerized encystomatosis was the probable diagnosis, but the examination of the blood introduced a doubt. The white cells were 12,800, there were numerous neutrophil myelocytes and some myeloblasts, and, further, there were nearly 7,000 nucleated red cells to the cubic millimetre, about half of which were normoblasts, the rest megaloblasts. A second count, a week later, gave 9,400 whites with the same picture as before and the same number and proportion of nucleated reds. The blood picture was that of an acute myelocysthaemia, the eosinophil and basophil excess at the chronic type was absent. The alternative diagnosis was widespread metastatic cancer in the bone marrow, which may produce a blood picture resembling leukaemia, and which was obviously more likely in this case. The lady returned to London and died in Westminster Hospital about six weeks later. Dr. Hildred Carhill kindly wrote to me about the subsequent history. A fortnight after I saw her the white count was 8,000—neutrophil polymorphs 59 per cent, lymphocytes of all forms 40 per cent, eosinophils 1 per cent, no myelocytes, and no nucleated reds. The spleen had returned to normal in size. A later count was almost exactly similar. At the post-mortem examination cancer was found in the liver and ovaries, but not in the bones examined, and indeed, in view of the later counts, it was not to be expected. One is almost driven to the conclusion that my findings represented an erythroblastic and leucoblastic crisis resulting from the prolonged anaemia.

CHRONIC LYMPHATIC LEUKAEMIA

Chronic non-granular or lymphatic leukaemia is much rarer than the granular form, and less dangerous to life as a whole. I have seen cases, ultimately fatal, in which the first glandular enlargement—which had never disappeared—had been noticed eighteen and twenty years either respectively. Both these patients had been in fair health until a year or two before the end. In such cases the process almost certainly starts in the lymphatic glands and gradually involves one group after another, as these the process almost certainly starts in the lymphatic glands and gradually involves one group after another, becomes completely involved. There is no reason why the process should not start in any bit of lymphatic tissue in the body but a start in such extraglandular lymphatic tissue as the follicles in the bronchi or the intestine would mean an almost immediate spread to glands, and an apparent glandular onset. In cases where the process starts outside the bone marrow, the chronicity or acuteness of the individual case seems to depend entirely on the period when the marrow becomes involved, and on the rate at which the marrow space is filled by lymphocytes. When this occurs the marrow is available for erythroblast proliferation and in anaemia which is practically aplastic in character the results are severe.

But this anaemia is rarely so severe as in the acute myeloblastic and lymphatic forms in which the starting point is in the marrow itself. Nor is the tendency to haemorrhage so great on the whole as in the chronic myelocysthaemias. The chronic lymphatic cases are much more apt to die from the pressure effects of the glands, which are so much more uniformly enlarged in this form than in any other from the tendency to thrombosis of veins, and from the interference with function due to the infiltration of vital organs. As internal glands may sometimes be the first affected, pressure effects may occur early, and may cause puzzling clinical pictures until the blood is examined. An interesting example of this difficulty presented itself about eighteen months ago.

A lady who had complained of shortness of breath for about six weeks developed pleurisy with effusion without rise of temperature, about a fortnight before I saw her. The effusion had to be tapped several times before it ultimately settled down. Her doctor, who had gone over all the usual possible causes without result, examined her blood and found a great excess of lymphocytes. My first count

was red cells 4,700,000, haemoglobin 75 per cent, white cells 55,800. Of the whites 91 per cent were lymphocytes, degenerated lymphocytes, and there were no myeloblasts, many was no enlargement of liver or spleen and enlarged gland could be felt above the umbilicus and the right clavicle from elsewhere, but the veins in front of the chest were unduly prominent. The single gland was evidently in offshoot from a nodular mass. During the next six months while she was under observation the white cells fluctuated between 35,000 and 85,000, the proportions remained much as in the original films. The left lung was slightly dull all over, with diminished expansion. This was evidently a pleurisy resulting from the presence of a mass of leucocytes in the mediastinum. The patient is now well symptomatically, except for some weakness and shortness of breath on exertion, no other glands have appeared.

As these cases advance the white count usually rises slowly, and may reach a very high figure. In March of this year a man was seen who had noticed some enlarged glands at the back of the neck in 1918, other groups were gradually involved, and at his first visit all the external glands were greatly enlarged and the spleen reached the umbilicus. A diagnosis of lymphadenoma had been made but the blood had never been examined until he gave up his work elsewhere and settled in Edinburgh. My first count gave red cells 2,680,000, haemoglobin 50 per cent, and in the counting chamber the white cells were so closely packed together that the ruled lines could not be seen. When I had drawn the blood up to the figure 1 in the pipette it gave the astonishing figure of 2,224,000, which, so far as I have been able to find, is the highest count of white cells recorded in any condition. The films bore out this count: the white cells seemed quite as numerous as the red, and were practically all small lymphocytes. The patient was treated with arsenic. Six weeks later the glands had gone down to about a quarter of their former size—very often a general improvement in health. He had thrombosis of the veins of the left leg and generalized oedema with pleural effusion, he ultimately died suddenly. On this occasion the red count and haemoglobin were rather better than before, the white cells had fallen to 1,132,000, and were again practically all small lymphocytes. One neutrophil polymorph was seen in counting 500 cells. Though he had never been robust he had been able to carry on office work until a few months before his death.

ACUTE MYELOBLASTIC AND LYMPHATIC LEUKAEMIAS

Every physician is familiar with the hopelessness and tragic rapidity of the acute myeloblastic and lymphatic leukaemias. It has happened to me to see a patient who was well until a certain Saturday to make the diagnosis on the following Tuesday when he had a count of 10,000 white cells, and to see him die on the Friday with a count of 20,000. Recently the opportunity presented itself of observing throughout a case very nearly as rapid. The first recognizable symptom was epistaxis on the 20th of the month, there was haemorrhage later into the skin and from the kidney and bowel, and the termination was profuse haematemesis on the 29th. The red count was at first 4,800,000, haemoglobin 65 per cent. It showed a steady fall and on the 29th was 2,400,000, haemoglobin 42 per cent. This is typical of these cases. The rule is a gradual drop in red cells with a rising colour index—in this case from 0.6 to 0.87. If the case lasts long enough it is not uncommon to get a colour index above unity, and to find normoblasts as well as normoblasts in the blood. Another point of importance is the progressive diminution in the number of blood plates. The white count ran 9,300, 6,400, 10,400, 15,700. At first the polymorphs were 30 per cent, and at the end 10 per cent, at first also there were some neutrophil myelocytes and some eosinophils and basophils. The percentage of non-granular cells was about 60 in the first films of which 48 were myeloblasts. At the end the non-granular percentage had risen to 88, of which 65 were myeloblasts.

On analysing my cases it is evident that the acuteness of

the disease is nearly proportional to the percentage of myeloblasts and to the rate at which the percentage increases. Cases in which the true lymphocyte proportion remains high last much longer. Most of the cases of acute leukaemia are easy to diagnose, because though the leucocyte increase is small, there is usually an increase, and, except for the foregoing consideration, it matters little whether the excess is lymphocyte, myeloblast, myelocyte, or promyelocyte, or a mixture. The important point is the diminution of polymorphs and the great excess of cells with a round nucleus. With an ordinary Jenner stain all the forms except the myelocytes look very much alike, and special staining methods have to be used to differentiate them. But there is a group of cases which are very doubtful. Two recent examples will illustrate it.

The first was a lady of 52 who had suffered from melancholia for ten months. For a fortnight the temperature had been high. No physical signs of any kind were present to account for this. The white reaction was negative to typhoid and the paratyphoid fevers, and no enteric bacilli were found in the stools. There was no enlargement of external glands, the spleen dullness reached the border of the ribs, but the spleen could not be felt definitely. The white count was only 1,900. Not a single polymorph was seen, about 35 per cent of the whites were myeloblasts, the remainder lymphocytes. She died two days later.

The second was a man of 50 who was first seen because of an irregular pneumonia which had lasted for about a week. The white cells were 16,300 with only 70 per cent of polymorphs and no glycogen reaction. The comparatively low polymorph percentage made me suspicious that there was some condition behind the pneumonia. A week later the lung had cleared up and the white count had fallen to 7,600: polymorphs 54 per cent, lymphocytes 40 per cent, eosinophils 3 per cent, myelocytes 2 per cent, myeloblasts 1 per cent and a few normoblasts fairly numerous blood plates. A week later he was definitely anaemic: red cells 3,250,000, haemoglobin 50 per cent, white cells 6,000—polymorphs 22 per cent, lymphocytes 66 per cent, myeloblasts 8 per cent, myelocytes 2 per cent, eosinophils 2 per cent, a few normoblasts, blood plates few and large. Three weeks later (intermediate counts are omitted) the red cells numbered 1,000,000, haemoglobin 18 per cent, white cells 5,900—polymorphs 18 per cent, lymphocytes 66 per cent, myeloblasts 12 per cent, myelocytes 4 per cent, with numerous normoblasts, there were no megakaryoblasts. There was no enlargement of spleen or glands throughout and no haemorrhages—only progressive weakness as the main symptom.

How are we to class these cases in the absence of *post-mortem* evidence? In spite of the low white counts I can only regard them as acute leukaemias—the first probably mainly myeloblastic, the second mainly lymphatic. The differential count must be the criterion. The whole question, however, depends on the significance of myeloblasts occurring in the circulating blood—a subject too large for discussion here. It is to be hoped that some better method of differentiating myeloblasts in films than either Jenner-Giemsa or the oxydase reaction will be discovered and that some haematologist will undertake the embryological studies necessary to clear up our views of the phylogenetic relationship of these cells.

In connexion with the type of case just described, it will be realized that difficulty will sometimes arise in the diagnosis from pernicious anaemia, and this for two reasons—first, the not infrequent occurrence of a colour index of unity or above it in myeloblastic leukaemia and secondly, the high non-granular percentage in the differential count of pernicious anaemias. The first difficulty only arises if we are to regard cases of the type quoted as leukaemias, for increase of the white count is the rule in myeloblastic leukaemias, but is very rare in pernicious anaemia, and when it does occur is always a polymorph leucocytosis, and not a non-granular increase. The second difficulty may be illustrated by the following recent case. A man of 65 who showed all the characteristic signs and symptoms of pernicious anaemia had a red count of 1,500,000, haemoglobin 35 per cent, white cells 3,500, of the latter 84 per cent were lymphocytes, the remainder polymorphs. There were no myeloblasts. At first sight such a percentage makes one think of an acute lymphatic leukaemia, especially if the whites have not been counted, but the actual number of lymphocytes in the cubic millimetre is not really greatly increased. If we assume that the normal number of white cells per cubic millimetre is 7,000, of which polymorphs are 70 and lymphocytes 30 per cent, the actual number of polymorphs in the cubic millimetre will be 4,900 and of lymphocytes 2,100, while in the case quoted the lymphocytes are 2,940—not an overwhelming increase.

We are far too apt to use the percentages of the differential count, it would be wiser and would avoid misconceptions if we always quoted the absolute numbers of the different cells in the cubic millimetre. One safeguard in this bit of diagnosis is that myeloblasts are rare in pernicious anaemia, though they do occasionally appear. I have never seen them in sufficient number to cause error.

The difficulty of diagnosis between lymphatic leukaemia and glandular fever may be a very real one. Most cases of the latter disease are of short duration and do not present much difficulty, but in a recent case the temperature lasted for eight weeks and the enlargement of the glands nearly as long. The patient was a woman of 22, the enlarged glands were widely distributed on both sides of the neck but not elsewhere, there was slight enlargement of the spleen. The red side of the blood was a mild chlorosis, the red cells dropped slightly as the disease progressed. The first white count taken by her doctor, about a fortnight after the onset, was 16,000—polymorphs 14 per cent, lymphocytes 86 per cent. My first count, a few days later, was 12,000—polymorphs 26 per cent, lymphocytes 74 per cent, but in addition there were a great many degenerated lymphocytes with smeared nuclei, practically all the lymphocytes were "large." No myeloblasts were seen. Thereafter the count gradually dropped as the temperature fell and the glands diminished in size, and it has now for some weeks run about 3,000, with such proportions: polymorphs 44 per cent, lymphocytes (almost all small) 54 per cent, eosinophils and basophils 1 per cent each—that is to say, the blood picture is now that of a chlorosis with the polymorph leucopenia so common in that condition. Before I saw the patient the doctor had given the diagnosis as lymphatic leukaemia—a very natural conclusion on the evidence. I have heard of glandular fevers lasting a longer time, but have never seen one.

"A SARCOMA OF THE LEUCOCYTES"

No more need be said about the essential nature of leukaemia than that I regard it as a sarcoma of the leucocytes. The assumption that the disease is a sarcomatosis, however, only removes the difficulty a stage further back, and the problem is bound up with the question of what influence it is which in health keeps the normal number of leucocytes in the blood within such narrow limits. We know that the action of parasites, using the term in its widest sense to include bacterial and other organisms, can powerfully alter the count in disease in both positive and negative directions, that the proteins of food and probably other proteins and many other substances have definite actions. Does the interference of an infinite variety of substances keep the balance in health, and, if so, does it act directly on the bone marrow and the blood, or through the medium of some other organ? These questions require a definite answer before we shall progress much further in the understanding of leucocyte problems.

It is very striking when one examines the marrow of a myeloblastic leukaemic patient who has died with a count of, say, 20,000, to find all the tissue one can examine packed with myeloblasts to the practical exclusion of every other type of cell. The wonder is, not that the leucocyte count is increased, but that it is not vastly higher. One cannot resist the feeling that the excess of cells in the blood is there rather as an overflow than in response to any active call upon the marrow cells. Obviously the condition is widely present in the marrow before there is any evidence in the blood of its existence. A leucocytosis responding to an organismal infection occurs practically at once, and the marrow gets under way immediately, but never goes beyond the amount of hypertrophy required in each special instance. A leukaemia progresses in the marrow more or less steadily, in the acute cases progressively till death occurs. We do not know whether the spontaneous remissions which sometimes occur in the blood picture of the chronic leukaemias correspond to a real alteration in the condition of the marrow, if they do they are not more frequent than the retrogressive changes that occur in some tumours. It is well to keep an open mind but until further research throws fresh light on the disease the neoplastic theory of its causation is the most logical and satisfying explanation.

Historical Notes

ON

THE SITE OF THE ASSOCIATION'S NEW HOUSE

BY

E. MUIRHEAD LITTLE, F.R.C.S.

THE British Medical Association is but following the example of the Dukes of Bedford in moving from the Strand to Bloomsbury, for in 1704 the Russells left their great house near Covent Garden, and occupied their new mansion on the north side of Bloomsbury, or, as it was then called, Southampton Square. At that time there was open country at the back of the new house, and the view of Hampstead and Highgate from the garden was much admired. Compared with the Strand, the northern part of Bloomsbury has but a short history, and even compared with the southern part, which includes Bloomsbury and Bedford Squares, it is modern Bloomsbury Square was inhabited by distinguished persons as long ago as the seventeenth century, whereas Russell Square and the streets and squares to the north and west of it were not built until the beginning of the nineteenth century. In the map of London and Westminster by John Lubbock, published in 1801, most of them are represented as planned but not yet built, and only a few buildings on the north eastern side of Tavistock Square are represented as already existing.* Among these was

Tavistock House, the site of which is now covered by the New House of the Association.

In the Crace collection of maps in the British Museum there is a "Plan of the Estate of the Duke of Bedford laid out for Building by James Burton, 1806," in which Tavistock House is indicated as already standing in its own grounds at the back of the Tavistock Square buildings already referred to (see Fig 1). Through the kindness of Lieut.-Colonel Evelyn Gordon, the present agent to the Duke of Bedford, we learn that this house was built by James Burton in the years 1795-96, and it appears in various maps published in the last

century as "Tavistock House." It faced north-west, having a road in front of it, which afterwards became known as Tavistock Place North. This road appears to have been at one time continuous with Crescent Place, which leads to the once notorious Burton Crescent, now called Cartwright Gardens. It was, however, never a thoroughfare, being blocked by railings and a strip of garden at the north eastern end, where Burton Street now is, and by railings and gates a short distance from the Tavistock Square frontage. The topography is shown with some approach to accuracy in Cruchley's New Plan of London (Fig 2). This is said to be "improved to 1833," though it is hardly up to date as regards Tavistock House, which was enlarged and divided in 1825, but it shows the garden ground at the back of the house which was coterminous, as it is to-day, with the garden of a detached house in Tavistock Place. This house (which, like Tavistock House, is given

an erroneous ground plan) was of some celebrity. To this dwelling that remarkable stockbroker and man of science, Francis Baily, four times President of the Royal Astronomical Society, removed when he retired from business, and here, during many years, he carried out numerous scientific experiments, culminating in 1841 in the determination of the density and weight of the earth. His public services in connexion with astronomy and exact mensuration were immense, and Sir John Herschel did not exaggerate when he stated that his revision of the star catalogues alone entitled him to rank amongst the greatest benefactors to astronomy. Baily died in 1844, without any royal recognition of his immense services, despite the fact that he had greatly benefited the navy by his successful efforts to reform the *Nautical Almanac*. The house was afterwards occupied, till 1877, by the well known architect, Sir Matthew Digby Wyatt.

The James Burton above mentioned was a very important and well known personage a hundred years ago, he was a speculative builder and contractor who built nearly all the newer streets and squares which cover the northern part of the Bedford Estate. Dobie quotes a statement to the effect that in forty years Burton had built 2,336 buildings in various parts of London, including Regent Street and the houses of Regent's Park, where he was associated with Nash. He became a very rich man, but in his later years he lost a great deal of his wealth in the development of St Leonards-on-Sea, to which new resort he ran a service of stage coaches. His son, Decimus Burton, is better known to fame as the designer of the arch at Constitution Hill (but not of the Duke of Wellington's statue, which once stood thereon), and of many country houses and villas. Burton's design for the arch included a quidring, perhaps such as that by another hand which has since been substituted for the equestrian statue of the Duke. He was so much chagrined by the erection of the latter that he made provision in his will for the payment of £2,000 to the Government if it would remove that monstrosity.

The original Tavistock House was occupied by various tenants, until in 1812 James Peery acquired and lived in it. He was a well known journalist and reformer, who was born at Aberdeen, and originally wrote his name Peire. Having failed as an actor he became a reporter and regular contributor to the *General Advertiser*. As such he reported the trials of Admirals Keppel and Palliser. He planned and edited the *European Magazine*, and afterwards, as editor of the *Gazetteer*, introduced the system of employing a succession of reporters for the parliamentary debates. In 1789 Peery and a friend bought the *Morning Chronicle*, which soon became the leading organ of the Whig party. Lamb, Hazlitt, Coleridge, and Campbell all contributed to it. Like other Liberal journalists in the days of revolution in France, Peery did not escape prosecutions and imprisonment, but he emerged from them triumphant and they only increased his fame. In 1792, for having printed an advertisement of the address passed at the meeting of the Society for Political Information, held at Derby five months before, he was charged with having printed and published a seditious libel. The proceedings dragged on for a year, but finally Peery was acquitted. Five years later he was in trouble with the House of Lords for sarcastically suggesting that "the dresses of the opera dancers are regulated there." For this awful crime he got three months in

FIG 1—Part of the plan of the estate of the Duke of Bedford laid out for building by James Burton 1806. Baily's house is shown standing back from The Parade (now called Tavistock Place). The Skimmers Land is still held by the City company of that name as trustees for Tonbridge School. Crace Collection Portfolio A.V. No 18.

FIG 2—The neighbourhood of Tavistock House from Cruchley's New Plan of London Improved to 1833.

*Strictly speaking the Association's New House is not in Bloomsbury proper: it is in the Parish and Metropolitan Borough of St Pancras and not in the Borough of Holborn to which Bloomsbury belongs. The northern boundary of the ancient Manor or Burgh of the family of the 1st Lord later known as Bloomsbury and included in the old Parish of St Giles in the Fields lies to the south east of Tavistock Square and Place.

Newgate, where he held levees of his friends, and where presents of game and other luxuries poured in upon him. In 1809 he was once more in the dock charged with the heinous offence of reprinting the malicious suggestion of the Hunts in the *Examiner*, that the successor of George III would have "the finest opportunity of becoming nobly popular." This time he was quickly pronounced not guilty. Perry had a country house at Wimbledon, and his neighbour, Lord Nelson, stood godfather to his daughter George Robins (*vide infra*) drew up the catalogue for the sale of furniture at the Wimbledon house in 1822.

Perry died in December, 1821, and a few years later one Thomas Hill, who had acquired the lease, obtained permission from the Duke of Bedford to convert the main house into three separate residences, it appears from the plans that two wings were added to the original house, one westward and one eastward, at an approximate cost of £5,875. Thus it is seen that the original Tavistock House had become Bedford House, and the name of Tavistock was transferred to an entirely new house adjoining it on the south-west. In 1842 the executors of the late Thomas Hill assigned the remainder of their interest to George Henry Robins. This was the celebrated auctioneer whose name was a household word in the middle of the last century, and whose hyperbolic and flowery descriptions of the properties which he sold became proverbial. In the *Ingoldsby Legend*, "The Babes in the Wood," he who would ill treat children is wined.

Be sure he who does such base things
Will ne'er stuff Conscience's clown.
His riches will make themselves wings
And his property come to the humble!
Then He—and not those he deceives
Will have no cause for sighings and sobbings
When he finds him self smother'd with leaves
(Of fat catalogues) heap'd up by Robins!

Robins became very rich and gave much in charity, and thus he has a special interest for us as a supporter of hospitals. On one occasion at Newgate he made a collection for the Royal Sanatorium Infirmary, holding a plate in the street outside the church. For this act of begging he was taken into custody as a rogue and vagabond and this embryo flag dragged ended in his being prosecuted before the magistrates at Dover. But no evidence was offered and at Wandstone Assizes he brought in action against the magistrates and was awarded £50 damages.

His three houses were at this time mentioned in the *Standard* as being for 1857 they appear as Nos 1, 2 and 3 Tavistock Villas. They were also known in the estate lists as 1, 2 and 3 Tavistock Place North, but in 1845 the two end houses were there referred to as Tavistock and Russell House.

CHARLES DICKENS

In 1851 Charles Dickens took Tavistock House then and for many years previous to the residence of his friend Frank

Stone, A.R.A. "In 1852 the original lease was surrendered and new leases granted by the Duke, as follows. The most eastern house (afterwards called Russell House) to Frank Stone, the central one (afterwards Bedford House) to John Bate Cudde, and the most westward one (afterwards Tavistock House) to Charles Dickens."

Thus the once youthful reporter and contributor to the *Morning Chronicle* had come to live, not in the same house, but in one of the same name and next door to that in which the celebrated proprietor and editor of the paper had lived and entertained the men and women of light and leading

of his day. In the *Chronicle* most of the *Sketches by Boz* had first appeared, and Dickens always spoke in the most affectionate terms of Perry's successor, John Black, under whom he served.

There has been much confusion between the two Tavistock Houses, and it has been repeatedly stated that Dickens lived in the same house as Perry, or in "a moiety" of it. We believe that the mistake is now for the first time corrected.

Dickens was of a restless and nomadic nature, seldom satisfied to remain long in one locality, and the nine years of his tenancy of Tavistock House was a much longer time than that spent without interruption in any other house except Gadshill. Chance or choice seems to have attracted him to the north-west quarter of London. As a child he stayed with his parents in Norfolk Street (now Cleveland Street), near the Middlesex Hospital, and when they moved to London it was to Bayham Street, Camden.

Then his mother put up her brass plate and attempted to run a school in Gower Street North, at "Miss Dickens's Establishment," Little College Street, Camden Town, and Johnson Street, Somers Town, next received them, and at one time and another Charles lived with his father in the Polygon and in Bentinck Street, Marylebone. He went to a day school in Mornington Place, Hampstead Road. After his marriage he lived in Doughty Street for two years, returning to the north-west, to Devonshire Terrace at the top of Marylebone High Street. When he went to Lausanne to write *Dombey and Son* he sublet this house, and, returning before the subtenancy expired, he took a house in 1847 in Chester Terrace, Regent's Park. On finally leaving Devonshire Terrace he went for a time to Osnaugh Terrace, and then, in 1851, to Tavistock House. Here he remained till 1860, but after he took the house at Gadshill he spent much of his time in the country. After 1860 he had bachelor quarters at various places in London, one of which, at 5 Hanover Terrace, Regent's Park, should be included in our list. Besides these twelve addresses he had others in other parts of London and if the London County Council were to affix plaques to all his dwellings it would cost it a considerable sum.

Frank Stone, who occupied first Tavistock House and the Russell House was in A.R.A., the father of Marius Stone, R.A. and a great friend of Dickens. The latter, in a letter

Charles Dickens in 1859. After the portrait by W. L. With R.A. in the Victoria and Albert Museum, South Kensington. It was partly painted at Tavistock House. (Reproduced by permission of the Secretary and Director of the Museum.)

TAVISTOCK HOUSE IN THE TIME OF CHARLES DICKENS

FIG 3—Tavistock Place North, showing Russell House (left), Bedford House (centre) and Tavistock House (right) with the entrance gate

FIG 4—Garden in front of Tavistock, Bedford and Russell House (1900) showing the backs of the houses in Woburn Buildings

FIG 5—Rear view of Tavistock House. Charles Dickens's mulberry tree is seen on the left. The mulberry tree is still in existence

FIG 6—The back room on the first floor of Tavistock House in which Dickens gave his theatrical entertainments

to his brother-in-law Austin, writes about his plan of turning Stone's painting-room into a drawing-room.² According to Mr. Kutton, Stone temporarily occupied Dickens's late dwelling in Devonshire Terrace, while Dickens was making alterations in Tavistock House.

The great Danish writer Hans Christian Andersen was the guest of Dickens, and has thus described the house:

In Tavistock Square stands Tavistock House. This and the strip of garden in front of it are shut out from the thoroughfare by an iron railing. A large garden with a grass plot and high trees stretches behind the house and gives it a comfortable look in the midst of this coal and gas steaming London. In the passage from street to garden hung pictures and engravings. Here stood a marble bust of Dickens so like him so youthful and handsome, and over a bedroom door and a dining room door were inserted the bas-reliefs of Night and Day by Thorvaldsen. On the first floor was a rich library with a fireplace and a writing table looking out

on the garden, and here it was that in winter Dickens and his friends acted plays to the satisfaction of all parties. The kitchen was underground, and at the top of the house were the bedrooms. I had a snug room looking out on the garden, and over the tree-tops I saw the London towers and spires appear and disappear as the weather cleared or thickened.

In his difficulties in trying to find room for the audiences of these performances, Dickens was advised to consult Mr. Cooke of "Astley's," then the most celebrated of circus-men. In *Forster's Life* there is an amusing letter from Dickens which, as it alludes to the drive and gates, may fitly be quoted here:

One of the finest things I have ever seen in my life of that kind was the arrival of my friend Mr. Cooke one morning this week (18th October 1853) in an open phaeton drawn by two white ponies with black spots all over them (evidently stencilled) who came in at the gate with a little jolt and a

rattle exactly as they come into the ring when they draw anything and went round and round the centre bed of the front court apparently looking for the clown. A multi-side of boys who felt them to be no common ponies rushed up in a breath less as they twined themselves like ivy about the railings—and were only deterred from storming the enclosure by the glare of the Inimitable's eye. Some of these boys had evidently followed from Actley's.

After Dickens gave up the house in 1860 it was occupied by more or less distinguished, or at least notorious, people. It is said that it was at one time used as a Jewish college or school. Then it was the dwelling of a lady whom the medical profession has good cause to remember. This was the singer Miss Georgina Welldon, whose actions at law and whose ability in conducting her own cases made a good deal of stir in the late seventies and eighties. The great French musician Gounod lived some months with the Welltons at Tavistock House and gave singing lessons in the drawing-room. Here he composed the music of *The Maid of Athens*, which he presented to Miss Welldon. At some time or other Eliza Cook, a minor poetess now almost forgotten, lived here. She was the authoress of "The Old Arm Chair" and other sentimental and popular poems.

William Collins, R.A., whose pictures were very popular and often engraved in the last century, lived for a short time in Tavistock Square, and there, in 1824, his son William Wilkie Collins the novelist, was born. As well known, he became a close friend and collaborator of Dickens and was a frequent visitor at Tavistock House during the latter's tenancy of it, when it was the meeting place of many distinguished people. The numerous of Dickens's tenancy formed the most brilliant period of his career. He was in the prime of life and in the fullest enjoyment of his great gifts. He came to be known to

act drop for this was painted by Clarkson Stanfield, R.A., in two days, and afterwards framed and sold at the Gade hill sale for a thousand guineas.

Buildings in which Carlyle lodged in 1831

The accompanying photographs show that the three houses were very pleasantly situated, shut off from the street by railings and gate looking across the drive and shrubbery on an extensive garden or field, and having at the back each its private garden which joined the large garden at the back of the north-western side of Tavistock Place. Tavistock and Bedford Houses were pulled down in 1800, and Russell House in 1901. The photographs which have been received from the Bedford Office, show Fig 3, a view of the entrance gates and the houses from the south west, and Fig 4 the field or garden across the road extending to the backs of the houses in Woburn Buildings, in No 6 of which Thomas Carlyle lodged for two months in 1831 when he was vainly trying to find a publisher on satisfactory terms for *Sartor Resartus* (Fig 7). Of it he wrote

It is a very beautiful sitting room an inner bedroom above (and John sleeps with George) for which we are to pay 25s weekly. Quiet and airy and among known people.

From the back windows of this lodging Carlyle looked upon Tavistock House, in which in after years he was to be a frequent guest. The houses in Woburn Building which is but a court, are small and do not outwardly offer much prospect of immensity. When Mrs. Carlyle arrived to share the lodgings they were found to contain bugs, and the couple migrated to Ampton Street. In Fig 5 is shown the back of Tavistock House and "Charles Dickens's millberry tree", in Fig 6 the back room on the first floor of the house where Dickens gave his theatrical entertainment. These views no doubt represent the houses and gardens much as they were at the time Dickens first took Tavistock House although in the half century which had elapsed when the photographs were taken the shrubs and trees must have grown or been replaced.

I am much indebted to Mr. C. Fitzroy Doll, F.R.I.B.A., the architect and surveyor to the estate, who has very kindly had copies made from plans which he took when the three houses were demolished, and who had the plan (Fig 8) specially drawn to show the relation between Tavistock House and the new building of the British Medical Association. Another plan (not reproduced) of the ground floor of all three houses shows that the second Tavistock House was entirely an addition to the old house, not in lining the western wing of the latter, while the eastern wing formed part of Russell House. Fig 9

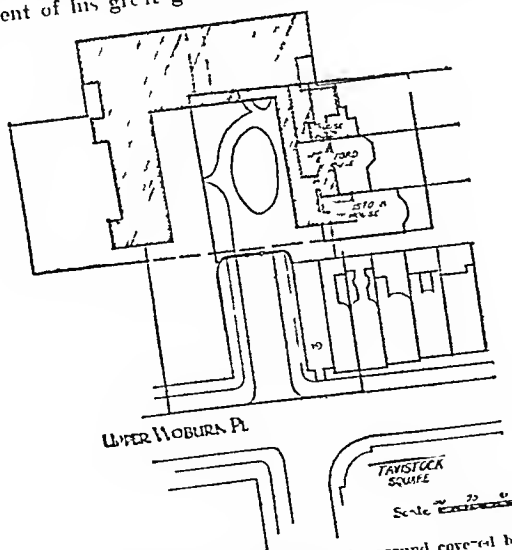

FIG 8—The hatched area shows the ground covered by the new building superimposed on the plan (in outline) of the old Bedford and Tavistock Houses.

the Medical House, *Hard Time*, *Little Dorrit*, *A Tale of Two Cities*, and *Great Expectations*. But the works were not enough for his restless energy. Beginning with the children's extracts on Twelfth Night, 1854, with the help of Mark Lemon and others, the smallest theatre in the world became celebrated and at every performance it was crowded with the leaders of literary and artistic London. The children of Dickens and of Mark Lemon seem to have displayed in natural drama powers and the song of Miss Widdows introduced (by desire) into Fielding's burlesque of *Tom Thum* so affected Thackeray that he rolled off his sea in a burst of laughter. *The Inghouse* by Wilkie Collins was the first of the adult plays to be given. The

FIG 9

shows the first floor of Tavistock House in plan, including the theatre. In Fig 8 it will be seen that the end of the southern wing of the Association's new building covers part of the front portion of the house, including the staircase and a part of the theatre.

THE BRITISH MEDICAL ASSOCIATION: ITS HOMES IN LONDON AND ITS SPREAD THROUGHOUT THE EMPIRE.

THE OLD HOUSES OF THE ASSOCIATION (1871 TO 1925).

THE new house of the British Medical Association, graciously opened by the King last Monday, is the fifth it has occupied since, in 1871, it established its headquarters in London. The reason for these changes was not restlessness or inconstancy, but steady growth.

The purpose of the Association has not changed in the ninety-three years of its existence though the means it uses to attain its purpose have developed and expanded. There can be no doubt that Charles Hastings and the provincial physicians and surgeons who gathered round him at Worcester in 1832 would have been in full sympathy with the aims and objects of the British Medical Association to-day.

For a period there was a risk that the Association might determine to remain provincial. Had that policy prevailed it could not have attained the position it holds to-day of the great all-embracing medical institution carrying its organization directly or indirectly, but for the most part directly, into every part of the British Empire.

The fortunes of the British Medical Association have been very closely interwoven with those of its journal. In 1844 the Provincial Medical and Surgical Association, as it was then called, took over the *Provincial Medical and Surgical Journal*, which had been established four years earlier by two members of the Association. In 1856, by a unanimous

vote, the names of the Association and of the journal were changed to the British Medical Association and the British Medical Journal respectively.

Though the Association had many strong supporters who believed in its future, and though the results were very encouraging in some respects (and in particular in the interest it was arousing in social questions having a medical aspect), its growth during the third quarter of the nineteenth century was slow, and its position was far from satisfactory from the financial point of view. In 1871 the members numbered 4,403, the

Plymouth) that the management of the Association was in an unsatisfactory state owing chiefly to defective organization and supervision, and recommended that a business man should be appointed secretary, that his office should be in London, that he should collect subscriptions, manage the Journal, and obtain advertisements for it, be responsible for all the preliminary arrangements for the Annual Meeting, and act as clerk to the Council and committees and at general business meetings. These recommendations were accepted, and Mr. Francis Fowke, then house governor and secretary of the General Hospital, Birmingham, was selected for the post. The Association at that time was particularly strong in Birmingham, and its policy was in large measure influenced by a few active members resident there. It required some faith and courage to give up an appointment which if not offering promise of distinction in the future, was capable of expansion and was at least a certainty. But Fowke was imbued with a very real respect for the profession of his father, who had been a well-known surgeon in Wolverhampton, and was fortunately possessed of some private means.

He found the business of the Association and the management of its Journal conducted in two rooms over a shop in Great Queen Street, a small thoroughfare running eastward out of Drury Lane. Hart, who was in practice as an ophthalmic surgeon, edited the Journal from his consulting room, first in Queen Anne Street and afterwards in Wimpole Street. The Metropolitan Counties Branch was at branches then went, large and active, so that Fowke came at once into a friendly atmosphere, and the honorary secretary of the Branch, the late Dr. Alexander Henry, became Assistant Editor. Henry did most of his work in his own small house in the North of London, paying short visits on one or two days in each week to the manager and the printer.

Mr. Fowke brought to the duties of his new office force and tenacity of purpose, and quickly introduced strict business methods into the management of the Association's affairs. With this combination of a Journal conducted with enterprise and constant attention to the needs of professional readers, and of efficient business management the finances of the Association were soon placed on a satisfactory

FIG 1—Offices in Great Queen Street. X shows one of the two rooms occupied by the Association from 1871 to 1878. The additional accommodation taken in 1874 was in the next house the ground floor window of which is seen to bear the name of the British Medical Journal.

total income of the Association was £5,261, and the balance of income over expenditure was £38.

The BRITISH MEDICAL JOURNAL had at that time been edited for several years by Mr. Ernest Hart, who had devoted his remarkable energy and abilities to its conduct with so much success that its circulation had risen to over 7,000 copies weekly. The unsatisfactory position of the finances of the Association was, therefore, all the more disappointing.

The Establishment of a Central Office in London

In 1871 the Committee of Council of which Mr. W. D. Hubbard of York was chairman, Dr. R. W. Falconer of Bath being treasurer, reported to the Annual Meeting (at

FIG 2—The house 1st Strand occupied by the Association from 1878 to 1885.

basis, and in 1874, when Mr George Southam of Manchester was Chairman of Council and Dr Paleoner still Treasurer, increasing business required, and the financial position justified, the taking of larger premises next door, at a rental of £30 a year. A photograph here reproduced (Fig 1) shows the offices in Great Queen Street at this time. Mr T Richards, whose name appears on the front of the shop, printed the JOURNAL from 1853 to 1878.

The Association's First House in London (1878-1886)

In that year the Association decided to undertake the printing of its JOURNAL, premises suitable for the purpose and to the then income of the Association were leased at 151, Strand. The Chairman of the Council when this first move was made was Dr Alfred Carpenter of Clowdon, and the Treasurer Mr W D Husband of York, upon whom and on Mr Powke the responsibility rested. The upper part of the new house (Fig 2) was occupied by the printing department, but the Committee of Council had a room for its meetings capable of seating thirty to forty persons, and a small room, stolen from a landing by the erection of a glazed wooden screen, was continued for the use on publishing days of the Assistant Editor, who was soon joined, as Sub-editor, by Mr Alban Doan, F R C S, who happily still lives and is engaged on the work of classifying and cataloguing the collection of instruments in the Royal College of Surgeons of England.

The Second House (1886-1907)

The membership of the Association the circulation of its JOURNAL and the receipts from advertisements all now began to show rapid expansion, and each year a substantial balance of income over expenditure, varying from £1 500 to £3 500, was shown on the year's working. In 1886 an opportunity occurred of acquiring the lease of the house 429 Strand formerly occupied by an insurance company. A sum of £4 500 was given for the lease and a little over £5 000 was expended on furniture and on the necessary alterations of the building. In 1888 the Association was able to purchase for the sum of £3 200 the lease of the two adjoining houses—Nos 2 and 3 Agar Street while in 1895 it acquired for £750 the lease of Nos 4 and 5 Agar Street. The aspect and extent of the offices occupied by the Association from 1888 to 1907 are indicated in the photograph (Fig 3) here reproduced. In 1894 the Association acquired in £4 640 the freehold of two small houses in a court immediately behind the front building and ultimately by an exchange with the neighbouring leaseholders obtained an L-shaped site upon which the building indicated was erected. Eventually the Association required the freehold of the houses in the Strand and Agar Street, the total amount expended in acquiring the

site and the buildings on it and putting them in order was £85,000.

The Third House (1908-1925)

The improvement of the accommodation provided in the several houses became an urgent matter in 1904. Various circumstances contributed to bring this about. The reorganization of the Association in 1902, leading to the election of a series of standing committees and the appointment of a Medical Secretary—who took up the full duties of his office in 1903—placed a great strain upon the resources of the old buildings, such provision as was possible was made for the committees and the Medical Secretary and his staff, but it had to be recognized that it was altogether inadequate for the proper conduct of the work. The Library had outgrown its accommodation, and the room in which it was arranged, though finely proportioned and not ill adapted for a reading room, was so completely unsuitable for the meetings of the Council, of conferences, or of large committees, that it was found desirable to accept the hospitality of the Metropolitan Asylums Board, which placed its spacious board room at the disposal of the Council for the quarterly and other meetings. Altogether the premises were found too small and it was realized that some change had become imperative. At first it was thought that it might be possible to

obtain the needed accommodation by remodelling the house in the Strand and rebuilding those in Agar Street, and in its own. The matter was very thoroughly investigated by the Premises and Library Committee appointed by the Council, under the chairmanship of Mr Andrew Clark, with the assistance of statements and estimates prepared by the General Secretary (Mr Elliston) the financial aspects of the questions involved were very fully considered. After several alternative schemes for partial rebuilding, the Council accepted the recommendation of the Committee that the wisest, and in the end the most prudent and economical course, would be to demolish the whole of the houses on the Strand and Agar Street site, and to erect on it a new building specially designed to meet the requirements of the business of the Association.

Preparations of the plans were thrown open to limited competition and on the advice of Mr William Henman, F R I B A, the task was eventually entrusted to Mr Percy Adams, F R I B A, who was instructed to plan the ground floor and basement so as to be suitable for letting for business premises, the Association reserving for its own use the five floors above the ground floor. The work of demolition was commenced at Easter, 1907. The old house was razed to the ground, and for nineteen months, during the rebuilding, the work of the Association was carried on in temporary premises in Catherine Street, Strand. Possession

FIG 3—The buildings in the Strand and Agar Street occupied by the Association from 1886 to 1907.

FIG 4—The building erected by the Association on the site at the corner of Agar Street and the Strand (429 Strand) and first occupied at the end of 1907.

business premises, the Association reserving for its own use the five floors above the ground floor. The work of demolition was commenced at Easter, 1907. The old house was razed to the ground, and for nineteen months, during the rebuilding, the work of the Association was carried on in temporary premises in Catherine Street, Strand. Possession

was obtained of the new and enlarged premises in November, 1908, but the work of arranging the Library in the fine room provided for it was not completed until some months later. The General Office was established on the first floor, the Medical Secretary's on the second floor, and the Editorial Office on the fourth floor. The printing department was on the top story (fifth floor). The lofty Library gave an opportunity for a mezzanine between the first and second floors. This was used as an extension of the General Office, and the Medical Secretary's department eventually overflowed into the third floor. In this estimate of the space occupied by the Medical Secretary's department is included committee rooms. As the Association has twelve standing committees meeting in London, and as it is frequently necessary to appoint subcommittees or special committees, the strain upon the accommodation of the Medical Depart-

ment became increasingly great. This was one consideration which led to the search for a new site, another was that the house in the Strand provided no hall for large meetings such as a Representative Meeting, should one be called in London, nor for the conferences of representatives of Local Medical and Panel Committees, of which one at least is held every year, nor for large conferences between the Association and other bodies. Accordingly, the Council some years ago began to make inquiries, and after long search eventually found the site off Tavistock Square upon which there already existed a building, designed by Sir Edwin Lutyens, R.A., well adapted for the purposes of the Association, and including a large hall seating 500 people. The site had the further advantage of providing space for the erection of additional buildings should these become necessary in the future.

THE AUSTRALIAN BRANCHES AND THEIR HOMES

[Dr R. H. Todd, *Honorary Secretary of the Australian Federal Committee*, has been good enough to write for us the following account of the Australian Branches and their homes, and of the Federal organization in Australia.]

AUSTRALIA has six Branches of the British Medical Association one in each State of the Commonwealth. They are the New South Wales, the Queensland, the South Australian, the Tasmanian, the Victorian, and the Western Australian Branches. They are coordinated in their activities by the Federal Committee of the British Medical Association in Australia and have a medical

journal in common—namely, the *Medical Journal of Australia*. The Australian Medical Congress (British Medical Association) is constituted under the Federal Committee to hold sessions every year, every second year, or every third year as may from time to time be determined. The session is arranged for and undertaken by one or other of the several Branches in Australia or by the New Zealand Branch.

Four of the Australian Branches are the proud possessors of homes of their own, where they have their libraries and offices and hold their meetings, and the other two have their regular meeting places. The Branches are all vigorous institutions, alive to their responsibilities in promoting the medical and allied sciences, in maintaining the honour and interests of the medical profession and in carrying out the other objects of the British Medical Association in their own portions of the Empire. In all the public relations of the medical profession each Branch within its own State is recognized by the Government and the people as the organized body of the profession in the State and is competent to speak for the profession and in Commonwealth matters, the Federal Committee is looked to to act and speak for the whole profession in Australia.

The first three Branches to be formed were all recognized as Branches by the parent Association under its rules in the same year—namely, 1880. They were the Victorian, the New South Wales, and the South Australian Branches,

known respectively for some years after their formation as the Melbourne and Victorian Branch, the Sydney and New South Wales Branch, and the Adelaide and South Australian Branch. At that time the unit of the Association was the individual member, and not, as now, the Division or Division-Branch. There were in all the three Colonies in which the Branches were formed members of the Association who, for one reason or another, held aloof from the Branch. By the year 1902, however, when the Constitution was altered to provide that every member should be a member of the Branch in the area where he resided, not many members were affected by the alteration.

THE VICTORIAN BRANCH

The first Branch to be established in Australia was the Victorian and the following facts connected with its origin have been supplied by Dr A. L. Kenny. Early in the year 1879 Dr Louis Henry returned to Melbourne from Europe with letters from the President of the British Medical

Association empowering him to communicate with the members of the medical profession in the Australian Colonies with a view to the formation of Branches of the Association. The first provisional committee meeting was held at the house of Dr James Edward Nield, 165 Collins Street, Melbourne, on Thursday, September 11th, 1879. There were present Drs J. F. Neild, L. Henry, W. H. Cutts, J. Graham, M. Gillbee, Drs J. Jamieson, A. Morrison, McMillan, Mr J. Rudall and Dr Browning, all of whom are

FIG. 1—The House of the Victorian Branch.

now deceased. On September 25th, 1879, the first general meeting of the Branch was attended by thirty members and a Council was elected as follows: President, Mr Gillbee, Vice-President, Dr W. H. Cutts, Honorary Treasurer, Dr James Graham, Honorary Secretary, Dr Louis Henry, Drs Neild, McMillan, Jamieson, Browning and Morrison, and Mr Rudall. At its first meeting this Council at once put itself in communication with the medical profession in the other Colonies with a view to the formation of Branches of the Association in New South Wales, South Australia, Queensland, Tasmania, and New Zealand. The result was very gratifying so far as the first two of these Colonies were concerned. By the end of the year 1879 the Victorian Branch numbered sixty-two members.

The first Annual Meeting was held on August 6th, 1820, when the President, in his retiring address, disavowed any feeling of rivalry with the Medical Society of Victoria, members of which had furnished the bulk of the members of the Branch. Eighty-five members were on the roll at the second Annual Meeting on July 15th, 1881. It was pointed out that, without in any way hindering the progress or superseding the purposes of the older society (the Medical Society of Victoria), the Branch would take up subjects which, while strictly of a medical nature, had a more immediate relation to the general interest than those which were commonly discussed in medical societies, and, moreover, being in alliance with the Branches of the Association in the other Colonies, would be able to co-operate with them in the discussion of those broader questions with which purely local associations have less concern. The first Medical Society in Victoria was called the Port Phillip Medical Association. It came into existence in May, 1846, and was dissolved in 1857. The Victorian Medical Association was formed on May 7th, 1852, and the Medical-Chirurgical Society of Victoria on June 6th, 1854. These two bodies were amalgamated on June 18th, 1855, under the name of the Victorian Medical Society. This name was changed in the following year to the Medical Society of Victoria, and by it the society is known at the present day. The Victorian Branch of the British Medical Association and the Medical Society of Victoria, on January 4th, 1907, blended their constitutions in such a way that, to all intents and purposes, they became one body, membership of one implying membership of the other, and their councils and office-bearers being identical. Under this dual organization the Branch has the benefit of a grant of land, at the corner of Albert and Brunswick Streets, Melbourne, made to the Medical Society of Victoria in 1877, for the erection of a building for scientific purposes. A one-storied brick building was erected on the land, and the Medical Society of Victoria met there in its own "Medical Society Hall" for the first time on January 5th, 1878, when it celebrated its twenty-third annual meeting.

After the amalgamation of the two institutions, this building served as library, meeting-hall, and offices for the Victorian Branch of the Association until the present year, when it was demolished, and a handsome three-storied, well equipped modern concrete building has been constructed in its place. It contains on its ground floor a meeting hall capable of seating 350 persons, the library, 61 ft by 30 ft, is above the meeting-hall. A reading and writing room and council chamber and offices are also provided. On the ground floor is a large foyer, in which is placed the bronze memorial in memory of the members of the medical profession in Victoria who fell in the great war. On the third floor is a suite of rooms for the caretaker. The formal opening ceremony of the new home of the Victorian Branch took place on May 20th, 1925, reported in our issue of July 4th. The membership of the Victorian Branch is now approximately 1,200.

THE NEW SOUTH WALES BRANCH

The New South Wales Branch was recognized by the parent Association in the year 1880 at a time when there was no other medical society existing in the Colony. For several years previously the Medical Section of the Royal Society had served the purpose of the profession for the promotion of medical and allied sciences. In the first year

of its existence the New South Wales Branch had forty-two financial members. The numbers increased from year to year, and the activities of those members who had previously constituted the Medical Section of the Royal Society were transferred to the Branch. The membership of the Branch is now approximately 1,450. It is the largest Branch of the Association outside the United Kingdom. Of the original members the following still take an interest in its affairs: Dr. A. J. Brady, Dr. W. E. Warren, Sir Charles McKellar, Dr. T. H. Frischi, and Dr. William Clusholm.

For the first thirty years the meetings of the Association were held at the Royal Society's hall in Elizabeth Street, Sydney, and the Council for many years met in the library of the Editor of the *Australian Medical Gazette*, then the journal of the Branch, at 121, Bithurst Street, Sydney. In 1910 the Branch decided to have a building of its own. Land was purchased with a frontage of 64 ft to Elizabeth Street and a depth of 80 ft, and on it was erected the building of six stories which is known as the British Medical Association Building (30-34, Elizabeth Street, Sydney). The Branch went into occupation of its new home in March, 1911. The premises were so constructed that the first floor comprised a meeting-hall and library, together with reading rooms and offices for the Branch; the other floors were offices and business premises, which could be leased to suitable tenants. The purpose of the Branch in so constructing the building was that it should not only be a habitation for the Branch, but, in course of time, a source of revenue to enable it the better to carry out the objects of the Association in New South Wales. The names of Dr. W. H. Crago, now for thirty-six years the Honorary Treasurer of the Branch, and of Dr. G. H. Abbott, President for the year 1910-11 (the first graduate of an Australian university to fill that office), will always be associated with this building. It had its origin in their inspiration and foresight, and its successful completion was due to their enterprise. The management of the building has from its commencement been in the hands of Dr. Crago.

THE QUEENSLAND BRANCH

In Queensland it was not until 1894 that success followed efforts made from time to time for the formation of a Branch of the British Medical Association. As in most of the Colonies, attempts had for many years been made to organize the profession by the formation of medical societies. The first society of which anything is known was the Queensland Medical Association, which was founded in 1871. It had eleven members and lasted for nine months. In 1882 the Medical Society of Queensland came into existence. Its activities also were short-lived. It was, however, revived in 1886, and became an energetic and vigorous institution holding regular meetings for scientific purposes for many years. The funds of the old Queensland Medical Association of 1871, which were in the hands of trustees and amounted to £11 11s 3d, were transferred to the Medical Society of Queensland and were utilized by it for the purchase of books which, in course of time, became the nucleus of the present library of the Queensland Branch of the Association.

The Queensland Branch was brought into existence in 1894 on the initiative of Dr. I. Sandford Jellison, who was prompted to take steps for the purpose by Dr. Fletcher Little of London, whose acquaintance he had made when visiting England a few years before. The rules of the

British Medical Association at that time required that twenty-five members of the Association should requisition the Council for the formation of a Branch. As there were only three members of the Association available in Queensland at the time, some organization work was needed to augment their numbers. This was undertaken and resulted in a meeting being convened, the necessary requisition was duly made by twenty-five members, and the Queensland Branch was recognized by the Council in 1894. The inaugural meeting of the Branch took the form of a convocation at which His Excellency the Governor of Queensland, Sir Henry White Norman, G C B, and other distinguished visitors were present. In 1899 most of the members of the Medical Society of Queensland were also members of the British Medical Association, and a fusion of the society with the Queensland Branch of the Association was brought about mainly by the enterprise of Dr A B Brockway, who was for many years the honorary secretary of the Branch.

The Branch at that time numbered 108 members. It soon began to grow too big and to be too active to be without a fixed abode, especially as it had a library which required housing. Being merely a collection of individuals, the Branch was not competent to own land, but the difficulty of procuring a home was overcome by arranging for a number of members to become incorporated as the Queensland Medical Land Investment Company, Limited. This company then purchased the premises which are now known as the British Medical Association Building, Adelaide Street, Brisbane. This building consists of three stories, the lower two of which

FIG 3—The House of the Queensland Branch

a company, called the B M A Hall Company, Limited, composed of members of the Branch, was formed, and a building, which previously belonged to the Y W C A, was purchased in 1913, situated on the west side of Hindmarsh Square, having a frontage of 40 ft to the square and a depth of 100 ft, and a rear frontage to Hyde Street. The building, which was erected in 1902, is constructed throughout of red brick with grey cement facings. It consists of a basement occupying the whole area and of two floors. On the upper floor are five rooms leased to tenants. The ground floor consists of a large meeting-hall and three rooms, one of which is let to a tenant. The other rooms are the offices and library of the Branch. The hall measures 40½ ft by 30½ ft. It is furnished with blackwood chairs having an extended right arm rest for writing purposes, and handsome blackwood bookcases along the walls. At the entrance of the hall is a large ante-room and at the rear is a gallery and two small sitting-rooms.

In 1913 an appeal had arrived from London for help in erecting memorials in England to the memory of the late Lord Lister, which suggested the desirability of making a local memorial and naming the hall of the new British Medical Association building the "Lister Hall." The new hall was opened on June 28th, 1914, when, at the invitation of the President of the Branch (Dr B Poulton), Sir Harry Allen, the Dean of the Faculty of Medicine of the University of Melbourne, formally dedicated the hall to the memory of Lord Lister on behalf of the members of the Branch, and, at the same time, unveiled a portrait in oils of Lord Lister which had been presented to the Branch by Dr H S Newland. Sir Harry Allen then delivered an address on Lord Lister and his work.

The membership of the South Australian Branch is now approximately 340.

THE WESTERN AUSTRALIAN BRANCH

The next Branch to be formed was the Western Australian Branch, it was founded in August, 1898, and was duly recognized as a Branch of the Association in 1899. In that year it had 47 members, ten years later the number had risen to 98. In 1919 the number was 136, it is now 180.

THE TASMANIAN BRANCH

The last of the Australian Branches to be formed was the Tasmanian Branch, which was formally recognized by the Council in 1911. It has its headquarters in Hobart, and its regular meetings have always been held at the Royal

FIG 4—The House of the South Australian Branch

THE SOUTH AUSTRALIAN BRANCH

The South Australian Branch was formally recognized by the Council of the British Medical Association in 1880 at a time when there were a large number of medical men in Adelaide, especially those associated with Adelaide University, who were keenly interested in the progress of medical science. During the early years the meetings of the Branch were held first in the board room, and afterwards in the out-patient waiting-room, of the Adelaide Hospital. Later the University generously provided accommodation for the monthly and the annual meetings. In 1911, on the initiative of Dr W T Hayward, C M G, a movement was started to require a home for the Branch. As the result of his efforts and those of Dr H S Newland C B E, D S O, the then honorary secretary of the Branch,

Society's House in Macquarie Street, Hobart, which the members of the Branch regard as their home. Prior to the formation of the Branch, the members of the medical profession in Tasmania belonged to the Medical Section of the Royal Society of Tasmania, which was established in 1897 with the object of allowing members of the Royal Society who devoted their attention to particular branches of medical science fuller opportunities and facilities of

meeting and working together with fewer formal restrictions than were necessary at the general monthly meetings of the society, and also to guard the interests of the medical profession in Tasmania. The pivot of this Medical Section was Sir James Wilson Agnew, the President, Dr R S Bright, the Vice Presidents, Dr G H Butler and Dr L L Crowther, the Honorary Treasurer, Dr A H Clark, and the Honorary Secretary, Dr Gregory Spiatt. Dr Gregory Spiatt's name has been closely associated with the Branch since its inception, and he was its first President. He is the director of the Australasian Medical Publishing Company, Limited, representing the Tasmanian Branch and one of the Representatives of the Branch in the Federal Committee. Tasmania being by far the smallest of the Australian States, the Branch has the smallest number of members—namely, 100, which, however, is two thirds of the total number of medical practitioners resident within its area.

THE FEDERAL COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION IN AUSTRALIA

With the development of the several Branches in Australia and the growth of their activities, the necessity for their co-ordination became more apparent year by year. Under the constitution of the Association, they had no relation to one another except through the Council and the Representative Body of the Association. On the other hand, they had many interests in common which called for local consideration and community of action. Among their greatest needs was a common journal, but, greater still, was the necessity for a Representative Body of their own. Australia had recently become a Commonwealth in which all the States were federated. There was a strong wish that nothing should be done to weaken the ties with the parent Association. The most obvious and appropriate method of organization of the Branches as between themselves was, therefore, some form of federation. The main difficulty to be considered was the great distance separating the centres of activity of the several States. It was inappropriate also that there should be centralization of the profession in any one State. The principle, therefore, was evolved of having a small committee in which each of the Branches should be equally represented, to consider all questions of common necessity to the Branches, and to act for the Branches in all matters of common concern. The constitution for the Federal Committee of the British Medical Association in Australia was accordingly drafted. It was adopted by each of the Branches in turn in 1912-13. Each Branch elected two of its members to be members of the Committee, and the first meeting of the Committee was held in Melbourne on May 27th, 1912, when Dr W T Hayward, C M G, was appointed Chairman, Dr (now Sir) George A Syme Vice-Chairman, and Dr G H Abbott Honorary Secretary. Dr R H Todd as Assessor was associated with the Committee in its inaugural work. The constitution was approved by the Council of the British Medical Association by letter, dated May 8th, 1914. The Committee, in the ordinary course, meets regularly twice in each year, the meetings being alternately in Sydney and Melbourne. In 1920 a meeting was held in Brisbane during the course of the Australasian Medical Congress (eleventh session).

The first task undertaken by the Federal Committee was the institution of a common medical journal for the Australian Branches. Its action in this direction resulted in the establishment of the *Medical Journal of Australia* as a weekly publication, which made its first appearance on July 4th, 1914.

The value of the Federal Committee to the Branches in Australia and to the Association as a whole has been fully recognized, and advantage was taken of amendment of the Articles of Association at the Annual Representative Meeting in 1923 to provide for a Federal Council of the Branches in Australia as a body within the constitution of the British Medical Association.

Apart from the establishment of a common medical journal for the Branches, the most important develop-

mental work entrusted to the Federal Committee has probably been in connexion with the Australasian Medical Congress. This congress, from the time of its inception in 1886 in Adelaide, has been held at three year intervals in the several capital cities of Australia and New Zealand, without having any definite permanent constitution providing for the continuity of its existence. The fact that it is now controlled and regulated by the Federal Committee and recognized as a British Medical Association Congress gives it both stability and permanence.

Dr W I Hayward retired from the position of Chairman of the Committee in 1922. The present Chairman, Sir George Syme, held the position of President of the first session of the Australasian Medical Congress (British Medical Association) Melbourne, 1923. The present Vice-Chairman, Dr W N Robertson C B J, is now on a visit to England as the Representative of the Federal Committee to attend—the invitation of the Chairman of Council, Dr R A Bolam—the ceremony in connexion with the opening of the Association's New House in Tavistock Square, Bloomsbury.

MEDICAL JOURNALS IN AUSTRALIA

Medical journalism in Australia has a long history. It may be said to have commenced sixteen years after the arrival in 1788, of the first fleet under the command of Australia's first Governor, Captain Arthur Phillip, R N, when Dr T Jamison, one of the surgeons of the first fleet wrote for public information an article on small pox which was published in the *Sydney Gazette* on Sunday, October 14th, 1804. The history of medical journalism in Australia is related in an extremely interesting article by Dr J H L Cumpston, the present Director-General of Health for the Commonwealth published in the first issue of the *Medical Journal of Australia* (July 4th, 1914) at page 11. In it Dr Cumpston gives the following tabulated statement of the medical journals published in Australia—namely:

1	<i>Australian Medical Journal</i> N S W	1846-1847
2	<i>Australian Medical Journal</i> Victoria after wards <i>Intercolonial Medical Journal</i> after wards <i>Australian Medical Journal</i>	1855-1914
3	<i>Medical Record of Australia</i> Victoria Afterwards continued as <i>Melbourne Medical Record</i> Victoria	1861 1863 1875 1877
4	<i>Medical and Surgical Review</i> — Australasian Victorian	1863 1864 1873 1875
5	<i>Australian Medical Gazette</i> Victoria	1869 1871
6	<i>New South Wales Medical Gazette</i> N S W	1870 1875
7	<i>Australian Practitioner</i> N S W	1877 1878
8	<i>Australasian Medical Gazette</i> N S W	1881 1914
9	<i>Intercolonial Quarterly Journal of Medicine and Surgery</i> , Victoria	1894 1896
10	<i>Journal of the Sanitary Inspectors Association of Western Australia</i>	1908

Of the ten journals enumerated New South Wales produced four and Victoria five. It was not until 1914 that there was a common journal for all the Branches. That year saw the commencement of the *Medical Journal of Australia*, which is now in its twelfth year. As stated above, the establishment of a common journal was the first task of the Federal Committee of the British Medical Association in Australia. At the time the Committee took the matter in hand there were two medical journals. One was the *Australasian Medical Gazette*, which was owned and conducted by the New South Wales Branch and published in Sydney, and which was accepted by the other Branches (except the Victorian Branch) as their official organ, the other was the *Australian Medical Journal*, conducted by the Victorian Branch and published in Melbourne. The Committee was faced with the constitutional difficulty that, not being a corporate body, it could not itself own a journal. A company, therefore, was formed, called the Australasian Medical Publishing Company, Ltd., with a constitution providing that all the members of the company should be representatives of Branches duly nominated by

the several Branches for the purpose. The members elect the directors of the company in the usual way, and the directors conduct the journal—the *Medical Journal of Australia*. Before the company was formed the Victorian Branch and the New South Wales Branch had generously handed over their respective journals to the Committee with a view to the new common journal being a Federal journal free of competition.

The company was registered in 1913 at Sydney, the first chairman of directors being Dr W H Craig (New South Wales), who had so successfully managed the *Australasian Medical Gazette* for many years in association with the late Dr C I Rennie, its editor. The other directors were Dr W N Robertson (Queensland), Dr F S Hono (South Australia), Dr Gregory Spiott (Tasmania), Dr W Kent Hughes (Victoria), and Dr the Honourable A J H Saw MLC (Western Australia).

The directors decided that an editor and a manager should be appointed who would give their whole time to the services of the *Journal*. Applications for the position of Editor were invited in England and in Australia. The present distinguished editor, Dr H W Armit, was selected from the many candidates. He was then associated with the *BRITISH MEDICAL JOURNAL*, and was well known as an organizer and for his work in medical research. At very short notice he gave up his career in England and came with his family to make his home in Australia. Within a few weeks of his arrival he produced the first number of the *Journal*. Shortly afterwards the great war broke out, and all the consequent difficulties affecting journalism had to be contended with. Nevertheless, he succeeded in establishing a paper which has now for many years been recognized among the medical periodicals of the world. The *Journal* had for some years to be set up and printed by contract, but in 1921 so good was its progress that it was able to dispense with the services of contractors so far as the type setting and composing were concerned. Now it has its own printing house, with a complete and up to date equipment and plant, and is not only altogether independent of outside assistance, but is undertaking general printing on its own account, especially of scientific and technical publications. A full and interesting illustrated description of the printing house, which is situated at Glebe, Sydney, is given in the issue of the *Journal* of April 11th, 1925. A copy of the *Medical Journal of Australia* is supplied weekly to every member of the Association in Australia in virtue of his membership, in the same way as the *BRITISH MEDICAL JOURNAL* is supplied.

THE AUSTRALASIAN MEDICAL CONGRESS

The institution now known as the Australasian Medical Congress (British Medical Association) was established in the year 1886 under the title of "The Intercolonial Medical Congress," and, as such, organized scientific meetings in the several Colonies or States of Australia and in New Zealand

every third year until 1905, the sessions being held as follows: 1886, Adelaide, 1889, Melbourne, 1892, Sydney, 1896, Dunedin, 1899, Brisbane, 1902, Hobart, 1905, Adelaide. After the federation of the Australian States as a Commonwealth the name of the congress was altered to the Australasian Medical Congress, and sessions were held under the new title as follows: 1908, Melbourne, 1911, Sydney, 1914, Auckland and 1920, Brisbane. At the meeting held in the year 1920, a referendum of the members of the congress was taken on the following question:

Are you in favour of the abolition of the Australasian Medical Congress as at present constituted in order that opportunity may be given of establishing congresses of the Australian Branches of the British Medical Association?

The voting on the question being in the affirmative, the following resolution was passed unanimously:

That the executive of the congress be empowered to wind up the affairs of the eleventh session of the Australasian Medical Congress and hand over to the Federal Committee of the British Medical Association surplus funds (if any) after the expenses of the congress have been met such funds to be passed on for the use of the future congresses of the British Medical Association.

The Federal Committee, at its subsequent meeting in February, 1921, resolved to establish British Medical Association Medical Congresses and to invite the co-operation of the New Zealand Branch. In another resolution it was determined that the objects of the congress should conform generally, *mutatis mutandis*, to those of the Annual Scientific Meeting of the British Medical Association. The first session of the congress under the new auspices was held in Melbourne in November, 1923, the President being Sir George Sime, F.R.C.S., chairman of the Federal Committee. The congress was an unqualified success and, as could be judged from the reports published in the *BRITISH MEDICAL JOURNAL* at the time, set a high standard for future sessions.

The late Sir William MacEwen accepted the invitation of the executive to attend this first session, and his distinguished presence as the ambassador of the Association was greatly appreciated by all the members as being further evidence of the feeling of kinship existing between the parent Association and its Overseas Branches.

The second session is being arranged by the New Zealand Branch and will be held at Dunedin in February, 1927.

In regard to membership of congress, whereas, under the previous constitution, every intending member had to apply to the executive on a form provided for the purpose and to be elected, under the present constitution every member of any Branch of the British Medical Association in Australia or of the New Zealand Branch is entitled to hold a member without election, and every other member of the profession is entitled to apply for election.

NEW ZEALAND.

The New Zealand Branch of the British Medical Association was established in 1896, when 104 members were enrolled. Its headquarters were at Christchurch, and the first permanent honorary secretary, Dr C Graham Campbell, held office from 1897 to 1902. By 1907 the membership had trebled and it was resolved to form Divisions within the Branch. In 1915 the number of members was 591 and in 1925 it had risen to 765. The Branch has fourteen Divisions: the Auckland Division has the largest number of members (170), the next in magnitude is the Wellington Division (117 members), the next Canterbury (99), and then Otago with 88. In March, 1924, it was decided to form a medical agency in connexion with the Branch office, to deal with the transfer of practices, the supply of locumtenents and the general safeguarding of the interests of the members of the Branch.

The Branch holds an annual meeting and at that held

in Auckland last year the President, Mr Currie Robertson, surgeon to the Auckland Hospital, said in the course of his address that in New Zealand many doctors had to carry on their practice entirely isolated in sparsely populated districts. Normally the New Zealand doctor worked alone, only occasionally, chiefly in the cities, did partnerships exist. In these circumstances the Divisions of the Branch form a talking point for the scattered workers, and though the membership of some of the Divisions is small they are of great value in affording opportunities for medical men to come together for discussion and to make or renew acquaintance.

As mentioned above, the next session of the Australasian Medical Congress is to be held at Dunedin, New Zealand, in February 1927. The *New Zealand Medical Journal*, the organ of the Branch, is published every two months, and 120 numbers have now appeared.

THE BRITISH MEDICAL ASSOCIATION IN SOUTH AFRICA.

We are indebted to Dr. D. Campbell Watt of Pietermaritzburg, President of the South African Committee of the British Medical Association, for the following notes on the history and present position and prospects of the Association in South Africa.

In 1888, at a meeting of the South African Medical Association held at Cape Town, it was resolved that the local division of the South African Medical Association should merge itself in the British Medical Association and become a Branch thereof. This resolution was duly carried into effect, and the Branch was called the Western Province Branch (Cape of Good Hope).

Five years later the Eastern Province Division of the South African Medical Association also became a Branch of the British Medical Association. Shortly afterwards the Griqualand West Branch was formed at Kimberley, and in 1896 the Natal Branch followed suit. The Transvaal Branch was next added to the number, while the Border Branch was formed in 1906 as an offshoot from the Eastern Province Branch. The Transvaal Branch by a process of fission later on became the Witwatersrand Branch and the Pretoria Branch and in 1913 the Natal Branch was split into the Natal Coastal and the Natal Inland Branches.

In 1912 the Rhodesian Branch was formed, and the Orange Free State and Basutoland Branch came into being in 1913, at the time of writing a new Branch is being formed in Port Elizabeth and district.

The South African Branches, therefore, are now eleven in number, and in most cases they have been formed from antecedent societies.

THE SOUTH AFRICAN COMMITTEE

Although the various Branches of the Association in the different Colonies and States exercised a salutary influence within their own spheres, especially on the legislative bodies in matters of public health and other legislation, in addition to the ordinary activities common to medical societies, yet it was felt that it was essential that there should be some combined body representing the entire Association in South Africa, able and willing to voice the views of the profession as a whole.

In 1906 the Western Province Branch therefore moved in the matter, and in 1909 the Central Council approved of the scheme submitted by the Branches for the formation of a South African Committee, subject to certain amendments, and it delegated many of its powers over the South African Branches to the Committee.

The Branches set to work, and by 1912 the Regulations of the South African Committee had been adopted and approved by the Council of the Association and the first office bearers appointed, the late Sir Kendal Friels, C.B., being its first President, Dr. Matthew L. Hewitt Vice-President, and Dr. D. Campbell Watt Honorary Secretary and Treasurer. The Branches represented at the inauguration of the South African Committee were the Western Province Branch, the Eastern Province Branch, the Griqualand West Branch, the Border Branch, all of Cape Colony, the Transvaal Branch, and the Natal Branch.

The existence of the South African Committee has been fully justified. Many subjects of interest to South African practitioners have been taken up, and some success has attended its efforts.

MEDICAL CONGRESSES

Shortly after the formation of the Committee it was decided that in the future the medical congresses should be held annually in the auspices of the British Medical Association, and in 1913 regulations were adopted governing the congress and appointing the South African Committee of the Congress as the organizing committee of each congress.

The 1924 Annual Congress has been held in Pietermaritzburg, as recorded in our last issue, p. 79.

MEDICO POLITICAL ACTIVITIES

The Committee was consulted by the Union Minister of Defence regarding the regulations dealing with the Medical Department of the Citizen Defence Force, and many of the alterations proposed by it were adopted. The necessity of appointing school medical officers was urged upon the Government with success. The establishment of a separate Department of Public Health, with a Minister, was advocated, and when the present Public Health Act was before Parliament the then President of the South African Committee gave evidence before the Select Committee, and prior to the bill being drafted he was appointed a delegate to a public health conference dealing with the proposed legislation, and his efforts proved highly successful in moulding the bill on the lines advocated by the South African Committee.

A consolidating Medical, Dental, and Pharmacy Bill has been before Parliament several times, and last year a vigorous attempt was made by Christian Scientists, chiropodists, and other cult practitioners to obtain State recognition under the bill. Evidence was given by them on the one side, and by the President of the South African Committee and other representative medical practitioners on the other side, before a Select Committee. The bill is again before Parliament this session, and as it stands contains no recognition of these cults. The profession is hopeful that the bill will go through as drafted in this regard, although there is a surprisingly large element of sympathy for these cults both in and out of Parliament.

Evidence was given by the President of the Committee before the Government Hospitals Commission, when he advocated the proposals which had from time to time been adopted at various congresses and by the South African Committee. Many of the Branches also sent witnesses to give evidence before that Commission. The Western Province Branch Parliamentary Committee has on several occasions held a watching brief for the Association, and done much to inform members of Parliament with regard to measures affecting the profession.

It was deemed advisable by the Committee to draw up a *Guide to Medical Ethics*, and the guide has received commendation from the medical press, and proved itself useful.

A voluntary benevolent fund has been established by the Committee, and arrangements made with several insurance companies for the issue of medical defence policies to practitioners.

THE FUTURE

The Association in South Africa had the pleasure of the presence of Dr. J. A. Macdonald, a Vice President of the Association and lately Chairman of Council, at the Congress held in Durban in 1920, and he paid a visit to most of the local Branch headquarters during his stay in the country. His visit was productive of much good.

The career of the British Medical Association in South Africa has not gone unchallenged. Several attempts have been made to establish a South African Association, the latest and greatest being within recent years, but on that occasion, by a small majority of the members, it was resolved to adhere to the British Medical Association, although a large proportion of the entire profession was in favour of a local association, affiliated with the British Medical Association. As a sequel to this position the Council of the Association most generously offered substantial financial aid in the appointment of an Organizing Medical Secretary for South Africa, but as a corresponding sum could not at the time be guaranteed by the Branches the Council has kept the offer open for a year.

Meanwhile the South African Committee and the Branches are making special efforts to increase the membership of the Association by the issue of appeals to non-members and the appointment of Branch organizing secretaries. At the present time the Association embraces about one-half of the practitioners in South Africa.

CANADA.

The organization of the British Medical Association was extended to Canada a good many years ago. The first Branch—Halifax, in Nova Scotia—was recognized in 1867, in 1891 the Montreal Branch and the Manitoba and North-West of Canada Branch were recognized, and in 1894 the British Columbia Branch. Afterwards Branches were recognized in Toronto, Saskatchewan, and New Brunswick.

Two highly successful Annual Meetings of the Association have been held in Canada—the first in Montreal in 1897 under the presidency of Dr. (afterwards Sir) Thomas Roddick, and the second in 1906 in Toronto, when Dr. R. A. Reeve was President. At the time of the meeting in Montreal the profession was much concerned to obtain from the Canadian Parliament an Act to remove certain legislative anomalies which hindered the free practice of medicine throughout the Dominion and also full reciprocity with this country. Dr. Roddick, as the leader of the Canadian profession in this matter, he visited every province to explain his scheme, and from his place in the Canadian Parliament urged its advantages year after year. The Canadian Medical Act was passed in 1902, but the Provinces which had hitherto had control, each in its own area, were slow to relinquish their privileges, and it was not until 1912 that it was possible to constitute the Medical Council of Canada, of which Dr. Roddick was elected the first President. It is not, we think, too much to claim that the two Annual Meetings of the British Medical Association held in Canada did much to assist the reformers there and to convince others of the possibility and of the advantages of the unification of the profession in the Dominion. Both meetings were attended by a large number of members from this country, and this alone was sufficient to convince our Canadian brethren of the keen interest the home members took in their difficulties—difficulties which had been overcome here—and in their welfare generally. After the Canadian Medical Council was established and legal unification was in existence, there still remained the task of bringing about the voluntary organization of the profession in Canada. The Branches of the Association in the Dominion languished and the Canadian Medical Association formed in 1867, when the Provinces were federated and a Dominion Parliament established, did not flourish.

After the war, in which the Canadian Army and its medical officers took so fine a part, the position of the Canadian Medical Association was taken in hand and it became apparent that this association, extended to the

whole Dominion, was in the opinion of the profession there better adapted to its needs than any reorganization of Branches of the British Medical Association could be. Discussions took place between the Canadian Medical Association and the British Medical Association which ended in the elaboration of a scheme for the affiliation of the Canadian and British Medical Associations. The Council at home was able to induce Sir Jenner Veall and the Medical Secretary (Dr. Cox) to accept a cordial invitation to visit Canada in the spring of 1924, and then the details of affiliation were finally adjusted. That scheme is now in force. Arrangements were made for intercommunication and the exchange of information, and members of the Canadian Medical Association were given the right to attend the Annual Meeting of the British Medical Association in this country and its Sections, to make use of the British Medical Association house and library, and to command the help of the central staff of the Association there. The Canadian Medical Association in addition to giving similar facilities to members of the British Medical Association undertook to nominate persons to act at Annual Meetings of the British Medical Association in the British Isles.

These plans are now working. Information is already being exchanged and more and more members of the Canadian Medical Association are resorting to the headquarters staff in London for help and advice on various matters. The British Medical Association has been able to arrange for some of its prominent members to visit Canada and to take part in the annual meetings of the Canadian Medical Association. Quite recently, as we mentioned a few weeks ago, the President of the British Medical Association Mr. Basil Hall, visited Montreal, Toronto, Winnipeg, Ottawa and other parts of Canada as a representative of the British Medical Association. He received a very warm welcome everywhere, and the address he delivered to the Academy of Medicine in Toronto is published in this issue. Mr. H. W. Carson, by invitation, gave addresses on surgery at the Annual Meeting of the Canadian Medical Association at Regina in June last. Further evidence of the success of the new plans is afforded by the fact that the largest and most representative delegation of Canadian medical men which has ever attended a meeting of the Association in this country has been present this week at the opening of the New Building, and will take part in the Annual Meeting at Bath.

WEST INDIES

The British Medical Association has been active in the West Indian Islands for nearly half a century. The first Branch, that in Jamaica, was founded in 1877, and the number of its members has increased to 64. The second Branch to be recognized was in British Guiana (1883), it has steadily maintained its membership, and publishes

reports of its work in a volume entitled the *British Guiana Medical Annual*. The Bermuda Branch was founded in 1886, and the Barbados in 1889. In the following year the Leeward Islands Branch was recognized. In 1892 the Trinidad and Tobago Branch was founded. Grenada Branch followed in 1916, and the St. Lucia Branch in 1923.

INDIAN AND OTHER ASIATIC BRANCHES.

The first Branch of the British Medical Association founded in India, or in the East, was the Bengal Branch organized in 1863 by the late Surgeon-Major Norman Chevers. The Branch was at first well supported and had a numerous membership, both of service men and of private practitioners—European and Indian. In 1867 Dr. Mohendra Lal Sarkar, a leading Indian physician read a paper advocating homoeopathy, to which he had become a convert. The discussion caused by this paper practically broke up the Branch, though it lingered on for a few more years. In 1879 an attempt was made to reconstitute the Branch, but the profession in Calcutta preferred to start an independent society—the Calcutta Medical Society. This body had a

successful career of some fifteen years. It published a monthly fasciculus of proceedings. For over half a century Calcutta, the former capital of India, has been unrepresented in the Association.

In 1882 the late Surgeon-Major C. W. Shirley Deakin, an I.M.S. officer of great ability and energy, started the North-West Provinces and Oudh Branch. Deakin enlisted a large membership, nearly two hundred, chiefly officers of the A.M.D. and I.M.S. but with a fair sprinkling of European private practitioners. Its meetings were held at Allahabad, and Deakin, as editor, published a monthly periodical, at first under the name of *Transactions*, which in 1885 became the *Indian Medical Journal*. This Branch came to grief in

1885 over a paper read by the late Lieut-Colonel (then Surgeon) Andrew Duncan, entitled "The insurmountable tendencies of State sanitation," the language of which was both intemperate and insubordinate, though the views of the causation of cholera advanced by Duncan were opposed to the theories then in official favour, strongly supported by Surgeon General J. M. Cunningham, the then head of the I.M.S., they have been proved by time to be correct. Duncan published Duncan's paper in the *Indian Medical Journal*, and supported it in a strongly worded leader. Both Derkin and Duncan suffered. Derkin went on far enough, and on his return was relegated to military duty in the Punjab. With his departure from Allahabad the North-West Provinces Branch died out. On his return from furlough he resuscitated it as the Punjab Branch. Most of the members of the defunct North West Provinces Branch joined the new one, which lasted for some four years. Derkin died of enteric fever at Jhulam on November 17th, 1889. After his death the Branch came to an end, as also did the *Indian Medical Journal*. Both the North-West Provinces and the Punjab Branches, though named after the provinces which were then headquarters, had members all over India.

The third Indian Branch, in date, was the South Indian and Madras Branch, founded on October 4th, 1883, and recognized in 1884. This is not only the oldest existing, but has been the most successful Indian Branch. It has now lasted over forty years, and in membership stands second only to Bombay. It publishes its *Transactions* monthly. In fairly rapid succession followed the Bombay and the (second) Punjab Branch in 1889, the Burma Branch in 1891, and the Deccan Branch in 1894. The last died out, or was in a state of suspended animation for some years, but has been resuscitated as the Hyderabad Branch. Three other Branches have since been added—Assam in 1908, Baluchistan in 1910, and Northern Bengal in 1922.

In April last the Association mustered eight Branches and over a thousand members in India, as follows:

	Recognized	Members
South Indian and Madras	1884	143
Bombay	1889	193
Punjab	1889	88
Burma	1891	63
Hyderabad (Deccan)	1894	30
Assam	1908	55
Baluchistan	1910	13
Northern Bengal	1922	13
I.M.S. officers not attached to any Branch		288
Other members outside area of any Branch		140
Total		1,026

There are four other Branches in Asia, outside India: the Ceylon Branch, recognized in 1887, with 206 members, Hong Kong and China, 1891, 169 members, Malaya, 1894, 202 members, and Mesopotamia, 1921, 45 members. Though far beyond the geographical boundaries of India, the last might almost be considered an Indian Branch, its membership consisting chiefly of R.A.M.C. and I.M.S. officers of the Indian Army. The Hong Kong and China Branch is increasingly active in spite of its insular position and local transport difficulties. Two meetings were held in 1923, but in 1924 it was decided to hold monthly meetings. At the invitation of the Branch to the Chinese Medical Missionary Association, a very successful joint medical conference was held in Hong Kong in January, 1925. The Ceylon Branch has published a journal for the last twenty-two years. The annual meeting of the Malaya Branch are now held alternately in the Federated Malay States and the Straits Settlements. Dr. J. W. Schriiff, honorary secretary of the Branch, acted as secretary and treasurer of the fifth congress of the Far Eastern Association of Tropical Medicine at Singapore in September, 1923. More than 300 medical practitioners attended from fifteen different countries, and nearly sixty papers were submitted dealing with tropical diseases and the opium evil. The active co-operation of the Branch and the energetic work of Dr. Schriiff contributed very largely to the value and success of the congress.

The Association has always used its influence to press the just claims of the great public medical services, each of which has, in turn, had cause to be grateful for the support given to it by the full weight of the profession in Britain, exercised through the Association. On at least three occasions during the last half century has the I.M.S. been helped by it. The first was over the "unemployed pay" question, in the early eighties, when the service had been over-recruited, till its strength was quite out of proportion to the number of appointments available, and a large number of juniors were drawing what was called "unemployed pay" while on general duty. Some of them had little work to do, as superintendents, assistants to senior officers in regiments, others, on choicest duty or similar work, were really working harder than the men drawing full pay. The second time was when the pay of nearly all ranks was considerably increased, in 1902. And the third was when both pay and pensions were again raised, after the war. On such questions also as commuted pay, specialist pay, and study leave, help to press the claims of the service has been readily given.

medical service, including nursing, in the Highlands and Islands of Scotland and otherwise providing and improving the means for the prevention, treatment and alleviation of illness and suffering therein." The Board of Health, which is the counterpart in Scotland, as far as regards powers and duties, of the Ministry of Health in England, administers this Act and as a result of its operation conditions of practice in the Highlands have been very greatly improved. Grants are made to individual practitioners, and in some instances a minimum income is guaranteed in return for which practitioners undertake to visit dependents of insured persons and persons of the crofter class at a standard scale of charges. The adjustment of the scale and of the grants is no easy matter, and finality has not been reached, but a fairly satisfactory working arrangement has been come to. A Highlands and Islands Committee of the Scottish Committee has been set up, and through it practitioners serving under the Act can express their views collectively. The Board of Health now recognizes that committee as representing the practitioners and regularly consults with it on all matters pertaining to the conditions of service.

Even apart from the Highlands, Scottish health legislation and administration differ considerably from English. The Public Health Acts are different, as is also the Education Act. The Insurance Act is the same in essentials, but is administered separately from England and differs in detail of administration. In all of these various spheres the Scottish Committee and its subcommittees find scope for activity and useful work for the profession. Testimony to the value of that work was made by the Secretary for Scotland in a recent speech, when he said that he believed the relationship between the Association and the Board of Health in Scotland had been not only of a friendly but essentially of a useful nature.

In a more restricted but still important sphere good organizing work has been done—namely, in connexion with contract practice in colliery areas. The Colliery and Public Works Surgeons' Committee, which, though not a committee of the Association, is organically connected with the Scottish Committee, succeeded some years ago in establishing a national rate of payment in substitution for the various district agreements formerly in force, and has successfully maintained the rights of the profession to reasonable remuneration.

The scientific side of the Association's work is likewise well maintained. The clinical demonstrations arranged by the Edinburgh and the Glasgow and West of Scotland Branches, and the clinical and scientific meetings of the Fife Branch and the South-Eastern Counties Division and other Divisions, are specially noteworthy.

The successful Annual Meeting in Glasgow in 1922 had a markedly stimulating effect, and the Annual Meeting which is projected for Edinburgh in 1927, when the centenary of Lister will be celebrated, is already being looked forward to with pleasurable anticipation.

The new Scottish House of the Association, the auspicious opening of which in Edinburgh was recently reported in

our columns,¹ marks a new era in the development of the Association in Scotland. Providing as it does imple office and other accommodation for the immediate purposes of the Association, it promises also to fulfil the function of a medical centre for Edinburgh and for Scotland. That the Scottish Committee may be trusted to promote and uphold the high ideals of the Association is evidenced by the speech of the chairman, Dr C. C. Douglas at the opening ceremony. Prefacing his remarks with a note of the extension of the membership in Scotland, he went on to say: "Such extension is all to the good. We must expand. It is true that the doctor is essentially a born individualist, he, like the soldier, feels that in the last resort it is his own hand, his own brain, may I add perhaps his own wits, by which he stands or falls. But just as the soldier, brave though he may be, is as nothing without the organization of the modern army behind him, so in our day no man can be at his best living apart from our great organization of the British Medical Association. And we have thus to offer him, that if he will join us, to his fine ideal of individual enterprise and energy there shall be added that other great ideal of devotion to a good cause, the maintenance of the 'honour and respectability' of the profession to which he belongs. It is an interesting thing to note how a great ideal attracts to itself the best men, and we see this in the history of our Association. From Sir Charles Hastings, our founder, who I like to think was a graduate of Edinburgh University in 1818, on to Sir Victor Horsley himself, there were always fine men at the head of its affairs. We should never, in a gathering like this, forget to think of Horsley, the father of this modern, self-governing, democratic Association of ours. Since his time we have always had good men at our head, and even now I am struck with the quality of the men whom one meets in the Council. There are men—I may not name them as some of them are here—who for intelligence, for sagacity, for devotion to our proper interests, might find an honourable place on the directorate of any of the great industrial enterprises. They say that we are a trade union. To that I reply that, while we may act as much like a trade union as may be done by the members of a learned profession, we work under a maxim—the fine old Roman law, *Salus populi suprema lex*—the which, were it acted upon by the great trade unions of this country, many of the evils under which we suffer would disappear. I say—and our records are all open to examination—that never in the history of the Association has anything ever been carried that is opposed to the general good of the community, and I feel certain that it never will. We have other functions. You may have noticed that we have above us the Scottish Meteorological Office of the Air Ministry. It appears to me that we ourselves act as the medical meteorological office—always on the look-out for storms, with this advantage, that we do something about these same storms when they do arise—a useful function not yet attempted by the other office."

¹ BRITISH MEDICAL JOURNAL June 14th 1925 p 1031

IRELAND

THE IRISH FREE STATE

THE Dublin Branch of the British Medical Association was established in 1877, its area corresponded approximately with that now included in the Leinster Branch. In 1895 it consisted of 120 attached and 202 unattached members, making a total membership of 322. The majority of these members resided and practised in the city of Dublin and its adjoining townships. The Leinster Branch now includes the counties of Dublin, Kildare, King's, Longford, Louth, Meath, Queen's, West Meath, Wicklow, and Wexford, except a small portion adjoining County Wexford. The south-western portion of Wexford with County Kilkenny and the County, Carlow, although in the Province of Leinster are not included in the Leinster Branch, and form a portion of the

area included in the South-Eastern of Ireland Branch. The Dublin Branch during its existence was prominently identified with Irish medico-political questions, and its leading members took an active part in the promotion of public health legislation and in the improvement of the position of Poor Law medical officers in Ireland. The majority of the members of the Dublin Branch were engaged in private practice, as is the case to day. They became members of the Association in order that they might be in a position to help their colleagues who were less fortunately placed in the public services and to share in the scientific side of the Association, and especially to receive its JOURNAL. In 1905 the Leinster Branch had a membership of 329, which fell in 1915 to 164 as the result of the increased annual subscription and had times generally

for medical practitioners in Ireland arising out of the European war. To day the membership of the Leinster Branch stands at 252. It must be remembered that a very considerable number of the younger members of the Association, especially of the Leinster Branch, leave Ireland each year to practise in Great Britain, the Dominions, and Colonies. The East and South of Ireland Branch was recognized in 1893, and in 1895 it had 41 attached and 104 unattached members. This Branch, with the South-Eastern of Ireland Branch, included all the Munster area and the extreme southern portion of Leinster. The East and South of Ireland Branch is now known as the Munster Branch, and includes the counties of Clare, Cork, Kerry, Limerick, and the North Riding of Tipperary. The medical population in Munster is small and scattered, as the province is almost entirely agricultural. The Munster Branch in 1905 consisted of 99 members, but owing to cruises similar to those which operated in Leinster the number of members declined. It has since increased, and the Branch has at the present time a membership of 102, which is the highest since its formation. The South Eastern of Ireland Branch was also recognized in 1893. In 1895 it had 37 attached members and 24 unattached. In 1905 its membership was 65, in 1915 it was 45, and in 1925 it was also 45. The South Eastern of Ireland Branch includes in its area the counties of Carlow, Kilkenny, Tipperary (South Riding), Waterford, and the south western part of Wexford which it adjoins the County Waterford. The Connaught Branch includes the Province of Connaught, it was recognized in 1903. In 1915 it had 31 members, and in 1925 this had increased to 40. Thus there are in the Free State four complete Branches. The Irish Free State counties of Carlow, Donegal, and Monaghan are included in the Ulster Branch with the six counties under the Northern Parliament. The four entire Branches in the Free State consist of fourteen Divisions. Of these, there are six in the Leinster Branch, three in the Connaught Branch, three in the Munster Branch, and two in the South-Eastern of Ireland Branch. There is also in the Free State the Monaghan and Carrigrohilly Division, which belongs to the Ulster Branch. The County Donegal (Free State) members of the Association are attached to the Derry and County Fermanagh Divisions of the Ulster Branch.

Besides the Branches and the Divisions there is a Standing Committee—the Irish Committee. The President, Chairman of Representative Body, Chairman of Council, and Treasurer are members *ex officio* of this Committee. The additional *ex officio* members are the Secretary of each Irish Branch and the members of Council representing Irish Branches. In addition there is one member appointed by each Irish Branch, but, if the Secretary of the Branch is a member of the Council, two members appointed by each Branch. Any member specially appointed by the Leinster Branch or by the Ulster Branch must be a practitioner not resident in Dublin or Belfast. Three to eight members selected by the Irish Committee at its first meeting each year complete the full list of members of the Irish Committee. The Irish Committee considers all matters specially concerning Ireland. It has its own Medical Secretary (Dr T. Hennessy) and its own Irish Offices (16, South Frederick Street, Dublin), where it attends to all Irish medical questions.

THE ULSTER BRANCH

In 1877 a number of medical men met in Belfast and resolved to form a Branch of the British Medical Association. It was decided to call it the North of Ireland Branch. Dr. James Cuning was elected first president, and Dr. John Moore honorary secretary and treasurer. Three general meetings besides the annual meeting are held usually in Belfast, but occasionally in other towns, and the average attendance is about 35. The Branch has grown steadily, and at the annual meeting this year, with Professor McIlwaine as president, the honorary secretary, Mr. H. P. Mulholland, M.C., reported a membership of 440. The agenda contained a list of a score of members who showed patients and demonstrated specimens. The clinical side of the Belfast Medical School holds a position almost of the time, and recognizes with gratitude the ever ready help of the Association and Journals. The representatives of the Branch on the Council and central committees are diligent in attendance, despite the distance, and offer their contributions to the discussions of the business of the Association at the same time they take back to Northern Ireland much useful information. Many clinical papers of scientific interest have been published from time to time in the *Journal* and have served to ventilate the views and discoveries of medical practitioners in Ulster and of the teachers in the medical faculty of the Queen's University of Belfast.

In 1884 the Annual Meeting of the Association was held for the first time in Belfast, under the presidency of the late Dr. James Cuning, professor of medicine in the then Queen's College. This meeting, at which a large amount of professional work was done, served to widen the outlook of the medical men of the Province, and acted as a stimulus to the scientific work of the school. In 1901-2, when the constitution of the Association was being reorganized, and Dr. J. S. Darling (Lurgan) was president of the Branch, and Dr. W. Caldwell (Belfast) honorary secretary, one of the tasks that had to be undertaken was the adjustment of the boundaries of the Divisions. Some difficulties were encountered, but they were eventually overcome, and the arrangements then made have continued in force with a few minor alterations until the present time. The Ulster Branch is practically co-terminous with the geographical area of Northern Ireland, and is very active, especially in Belfast. The Association met again in Belfast in 1909. Sir William Whittham, M.D., was President, and over 1,500 members attended. The late Sir John Biers gave the address in Obstetrics, and much useful work was accomplished in the scientific sections. This meeting served again to bring the unity of the profession home to those in Ulster who did not attend the annual meetings in other towns, or indeed rarely the branch meetings, and acted as a stimulus to the scientific work of the school.

The Ulster Medical Society is an old local society, serving the clinical wants of Belfast itself, and many country Fellows are assiduous in attendance at its meetings, it is in a flourishing condition, and publishes annual *Transactions* of much clinical value. The society and the Branch are complementary to each other, the friendliest relations existing between them, most Belfast practitioners are members of both, and in any general question of moment a committee formed from the councils of both is appointed to voice the views of the profession.

COMMITTEE ROOM A IN SOUTH WING

Country Life

THE NEW HEADQUARTERS OF THE BRITISH MEDICAL ASSOCIATION

DESCRIPTION OF THE BUILDING

THE GREAT HALL FROM ONE OF THE AISLES

on its side Bloomsbury is a region rapidly coming into its own once more after many years of comparative neglect, and the direct route from Kingsway to King's Cross is one which will presently be of the first importance. It is towards the northern end of this route that the House stands.

The New Building had been completed up to a certain point when it was taken over by the Government during the war. It was acquired by the British Medical Association two years ago from the Disposals Board on advantageous terms, the lease from the trustees of the Duke of Bedford's estate is for 200 years. The outside had to be completed and a great deal of work was necessary to the interior before it could be fitted, under the direction of Sir Edwin Lutyens, R.A., to the purposes of the Association.

The building has as many qualities as the site. Its broad façades were drawn by Sir Edwin Lutyens in sober

and austere mood, they were originally designed to house a religious organization, which may have had something to do with it. The plan is of that delightful enclosing U-shape which is the principal charm of so many of our collegiate and other buildings in which a great many people live and work together. The open space of the U is, however, approached through a broad passage which separates the central Court of Honour from Tavistock Square.

THE MEMORIAL GATES

Entering through this roadway (flanked on each side by buildings which will one day yield place to extended wings of the new edifice), the first objects that strike the eye are the beautiful Memorial Gates opening into the Court of Honour, and beyond the Gates the façade of the main block with its stately windows. The Gates or Remembrance are of wrought iron, and their design is founded on the choicest examples of eighteenth century work. They are surmounted by a bronze shield bearing on either side a legend lettered in gold: in front "Memoria

and praise," behind "Faithful hath been your warfare." They have been made by the Birmingham Guild to the design of the architect leafwork and scroll form the main feature. The total width of the gate and railings is 60 feet, the height at the centre is 24 feet. They have been erected by the Association as a tribute to the 574 of its members who fell in the war and whose names are inscribed in the *Book of Honour*.

COURT OF HONOUR, FROM SOUTH WEST ANGLE

[Country Life]

the main block, which are the most conspicuous feature of the building itself, naturally suggest the existence of some apartment of great consequence, and in accepting their evidence we shall not be disappointed. The Great Hall into which they admit an abundance of light is an

THE GREAT HALL

The lofty windows of

Photo]

THE GREAT HALL

[Contd. 1 p.]

imposing room approximately a double cube one hundred and thirty feet long. The simplicity of the whole building is here very logically maintained. The roof above this hall is supported on semicircular ribs of light steel framing, which remains unadorned except at each end where one bay is surmounted by a painted vault moulded to the shape of the ribs behind it. Modern conditions demand that beauty should be continued directly out of the useful and inexpensive, and in his treatment of the roof and vault of the Great Hall Sir Edwin Lutyens has complied with this demand in an extremely skilful way. The inside of the roof itself together with the many subsidiary members of the framing that support it are painted a nocturnal green, if such a colour exists (which we doubt), and against this shadowy background the semicircular ribs appear in narrow ribs of gold. The whole is supported upon a row of Corinthian columns whose shafts appear as though turned out of some brilliant peacock blue marble. This remarkable effect appears, upon close inspection, to have been achieved by means of paint. At the north end of the hall is a door, and at the south a gallery, running from end to end at the lower level of the roof is an ambulatory connecting the third floors of the north and south wings of the building.

Library and Common Room

Centrally below the Great Hall there runs a vestibule which connects the Court of Honour entrance with that in Burton Street. Entering this vestibule from the courtyard, there will be found on the left the Library, panelled in rare Spanish mahogany turned from the old house of the Association. On the right is the Members' Common Room, a spacious apartment with long French windows overlooking the Court; its walls are finished in white and a delicate pearl grey—the lightest and most ethereal grey

imaginable. A narrow black slitting helps to punctuate the subtle gradations of the walls. Below the rooms are large basement offices, containing the staff dining room and additional printing machine rooms, beside storage accommodation for the library.

Hastings Hall and Council Room

The windows of the Common Room and Library are repeated in the façade of the north and south wings, but the apartments lighted by them are several feet below ground floor, and are approached by flights of stairs and passenger lifts placed at each end of the wing. There are in the north wing, the Hastings Hall, capable of seating one hundred and fifty persons, and in the south wing the huge Council Chamber. Both halls are similar in shape and design, the ceiling springing from the walls in an ample concave entrenchment by the richly decorated over the window openings. The colour scheme in each hall is a combination of white with a pale ochreous yellow. Artificial illumination is provided by means of inverted bowls resting on little gilt pedestals of very interesting design. The floor of the Council room rises in tiers, and on these tiers are rows of comfortable seats upholstered in green leather. The walls are lined with oak panelling bearing the names of past Presidents, Chairmen, Gold Medalists, Editors, and other dignitaries and officials of the Association.

Court of Honour

The building covers eighteen thousand square feet, and has a total floor space of fifty thousand square feet. On its north it is flanked by a modern utilitarian garage, on its south by the Council's garden, whose pleasing sweep all springs from the old foundations of Tavistock House, where Charles Dickens lived and worked. Within the main courtyard the corners of the quadrangle are paved with

ELEVATION OF GREAT HALL (INTERIOR).

flagstones in a graceful curve, and the roadway leading from the Memorial Gates to the archway under the Great Hall surrounds a large circular grass plot with a wide kerb of white stone. A harmony in red, white, green, and grey is the result, with the delicate black tracery of the Gates in the foreground.

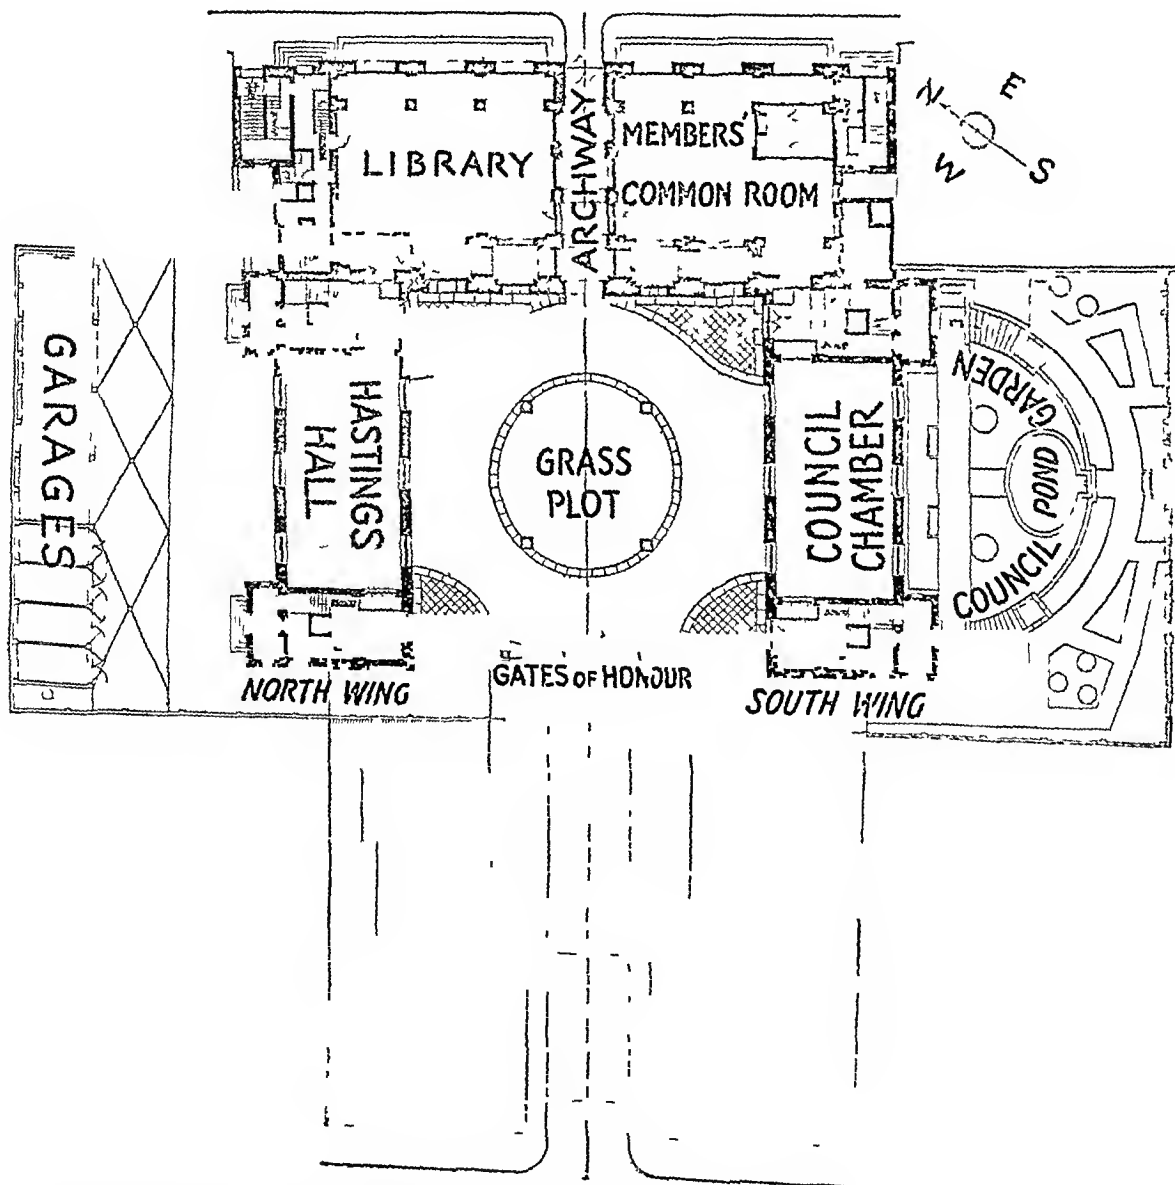

We may close this brief description of the new building with a note on the way in which the interior of the two wings has been laid out to take the various departments among which the central work of the Association is distributed.

Departmental Accommodation

On the first floor of the north wing, over the Hastings Conference Hall, are the general offices concerned with the business of publishing, subscriptions, and advertisements, on the second floor is further accommodation for the Finance Department, with rooms for the staff of the

Medical Insurance Agency. On the third floor is the Editorial Department, with rooms for the Editor, Assistant Editor, Sub-editor, and clerical staff. Above this, on the fourth floor, is the printing office, with type-setting machines, compositors' cases, and rooms for proof-readers.

The first floor of the south wing, over the Council Chamber, contains several fine committee rooms, and houses also the Intelligence Officer and her staff. The two floors above are allocated to the Medical Department. On the second floor are the rooms of the Medical Secretary, Deputy Medical Secretary, and Assistant Medical Secretaries, and the third floor accommodates the four committee clerks, the staff in charge of the card index and files, and the remainder of the clerical staff of this department. The fourth floor, arranged as a residential flat, is leased to the Financial Secretary, accommodation is also provided in the building for a resident medical officer.

GROUND PLAN OF SITE OF THE ASSOCIATION'S NEW HOUSE

The building as it stands is indicated by stippled shading; the sites of the proposed future extensions, on each side of the roadway from Tavistock Square, are shaded in vertical lines.

British Medical Journal.

SATURDAY, JULY 18TH, 1925

THE OPENING OF THE NEW HOUSE

ANOTHER chapter in the history of the British Medical Association began last Monday when the King, its Patron, visited the new site and formally opened the House in Bloomsbury which it has required and equipped. The members of the Association are deeply sensible of the honour paid to them, and to the profession they stand for, by this visit of their King and Queen. The close interest taken by Their Majesties in the progress of medical science and art, and their unflinching sympathy with the work of our profession for the relief of sickness and suffering, are matters of common knowledge. But this Royal Opening of the new House is so signal a compliment to our organization, its aims, and its work, that we make bold to describe it as a landmark in medical history. Physicians throughout the ages, and surgeons in later times, have had acknowledgement of their worth from State and Crown, but for the great body of general practitioners, who bear the heat and burden of the day, there has hitherto been little recognition. The British Medical Association, however, represents the profession as a whole, and in honouring this society our Sovereign honours us all.

Ever since it was founded in 1832 the British Medical Association has aimed at the integration of medicine for the common good, and this ideal is expressed in the Address presented to Their Majesties in the name of the Association on July 13th. During the past ninety three years specialization has spread far and wide and the conflict of material interests has threatened it times to split our ranks, but under the wise guidance of men of broad outlook the Association has continued to promote the advance of medical and allied sciences, and has gone far towards achieving its ideal of professional unity within these Islands and throughout the Empire. That its membership, now approaching 30,000, is world wide has been shown this week by the presence in our midst of leading medical representatives from Canada, Australia, New Zealand, South Africa, and India, and from distant Colonies and Dependencies, all bearing messages of loyalty and goodwill to the parent body. Moreover, hundred societies at home and abroad have sent delegates to join with us in celebrating this notable event in our annals. The position held by the British Medical Association in the public and professional life of this country is indicated by the fact that the Minister of Health accompanied Their Majesties as Minister in attendance, and that among those who awaited the Royal visitors, standing beside the principal officers of the Association, were the President of the General Medical Council, the Presidents of the two English Royal Colleges, Lord Dawson who represents medicine

at Court and in the House of Lords, and the Chief Medical Officer of the Ministry of Health and the Board of Education.

It was most fitting that these outward signs of the solidarity of our profession in this country and throughout the British Empire should have included the dedication and opening, by the Archbishop of Canterbury, of the beautiful Memorial Gates set up by the Association as a tribute to the 574 of its number who fell in the great war. In the minds of all who enter the new House for work or study or pleasure, the gates they pass through will "wake remembrance of these valiant dead."

The brilliant success of the ceremonies on July 13th was the reward of infinite care and attention to detail. Nothing that foresight could provide for was overlooked, and the gracious message of congratulation from the King and Queen, received on the following morning and printed at page 145, will be endorsed by all whose good fortune it was to witness the day's proceedings. The letter from Buckingham Palace expressing Their Majesties' admiration for this splendid building, their pleasure in opening it, and their appreciation of the excellence of all the arrangements, is one of those kindly and discriminating acts that round off a high compliment.

A PAGE OF HISTORY

THE account given elsewhere of the offices the Association has occupied since, in 1871, it established its headquarters in London is proof that the growth of its varied activities has been so rapid that the prudent anticipations of one generation have been found inadequate in the next. It has now a house amply providing for the administrative needs of to-day, and the control of a site which affords room for a great deal of expansion. The house now taken into use contains, in addition to offices for the three departments, a spacious Library, a members' conversation room, a fine Council Chamber, committee rooms, and a Hall capable of seating five hundred people, upon the design and decoration of which the architect, Sir Edwin Lutyens, has lavished his great powers.

Probably the most important decision the Association ever took was when in 1856, it resolved to take the name 'British Medical Association.' With its old name of 'Provincial Medical and Surgical Association' it could never have become the Empire wide institution it is. It had done a great deal of valuable work for the advancement of clinical medicine and the ancillary sciences, and also for the betterment of sanitary conditions, for the amendment of laws and regulations which in the new industrial era had become obsolete, and it had persistently sought for a reform of the Poor Law. This was work for the whole of Great Britain but without perhaps fully appreciating what it was about it had embarked on a still wider field. It had long been asking Parliament to establish a 'Medical Register' to which should be admitted only those who fulfilled certain conditions, the chief of which was that the applicant should produce evidence of having attained a certain standard of education by passing through a curriculum prescribed by the universities and medical colleges. This Register, during the transition period when the Dominions and Colonies were growing to nationhood, was Empire wide.

Later on the Association accomplished much for the public health and for social medicine generally, chiefly through the Parliamentary Bills Committee, which though it had a rather anomalous constitution was in effective body. But as the number of members grew the constitution of the Association itself got out of date. Its government was originally established on the representative principle by way of a large Council elected through the Branches, this Council met once a year and delegated its duties in the intervals to a Committee of Council. As the membership increased the constituents grew too big and a large proportion of members belonged to none. They were called 'unattached', they belonged to the Association in order to receive the *BRITISH MEDICAL JOURNAL* and to have the right to attend the Annual Meetings. In this way the organization came nearly to resemble that of a public company with an annual general business meeting open to every member, and a Council which, though not elected by the business meeting had functions very similar to those of a board of directors. This plan never worked well, and as the number of members grew it worked less well. The unattached members did not feel that they were responsible for the policy followed by the Association in medico-political matters and its influence with Parliament, with the Government, with the public, and with the profession itself, was thereby seriously impaired.

The main object of the alterations in the organization of the Association which were under discussion at the beginning of this century, and were embodied in the constitution which came into force in 1902, was to consolidate and extend the social and medico-political work the Association was doing and to establish its right to speak in the name of the whole profession. To attain the second purpose it was decided that every member of the Association should be a member of the Division within whose area he resided. In order that the work under the first head should be effectively done, a number of standing committees were set up, and a whole time Medical Secretary appointed to act as secretary of these committees, to prepare the business for them, and to carry out the instructions they might give. The work under this head very quickly increased, and the staff of the Medical Secretary's department had to be enlarged. There is now a Medical Secretary, a Deputy Medical Secretary, and two Assistant Medical Secretaries, besides a Secretary for Scotland and another for Ireland, with offices in Edinburgh and in Dublin respectively. At the present time there are fifteen standing committees concerned either with internal administration or with matters affecting the relation of the medical profession to public affairs. The standing committees work in consultation with the Council which meets seven times a year and is the executive of the Association. The Council reports its recommendations to the Representative Body, this body which contains representatives of all the Divisions both at home and overseas meets at least once a year and in it is vested the general control and direction of the policy and affairs of the Association. In this way the constitution of the Association has become strictly representative.

The attainment of this object was the second decision of supreme importance reached by the Association the first as has been said was that it should be an organization bounded in area only by the limits of the British Empire. In Australia it has six Branches one for each State they hold joint congresses periodically and are co-ordinated by a

Federal Committee, on which all the Branches are represented. In South Africa there are eleven Branches, and here is a committee (the South African) existence and joint congresses for scientific discussion are held. It is the great growth of the work of the Association in medico-political directions that has rendered imperative larger accommodation than was foreseen by those who were responsible for the erection of the house in the Strand which has just been vacated. The need was found for more committee rooms—the standing committees, of course, are empowered to appoint subcommittees, and sometimes the Council appoints special committees—and for larger rooms. The common room, originally provided for the use of members, was eaten up by the growth of the clerical staff and there was no large hall for meetings of the Representative Body, for conferences of representatives of Local Medical and Panel Committees, and for other largely attended conferences with other bodies—such, for example, as those that were held to discuss the policy the profession should follow with regard to voluntary hospitals. The new house in Tavistock Square provides for all these things, and the prudent course has been followed of acquiring the control of the sites at present occupied by the houses which lie between the building opened by the King last Monday and the main thoroughfare.

PRESIDENTIAL CHAIR GIFT FROM AUSTRALIA

At the Council meeting on January 18th last the Chairman stated that a letter had been received from Dr. R. H. Todd, Honorary Secretary of the Federal Committee of the British Medical Association in Australia, with regard to a proposal from the Australian Branches to present the parent Association with some gift for the New House, such as a chair, which should be made of Australian timber. On receipt of this letter a cablegram was sent to Australia saying that a President's Chair for the Great Hall would be most acceptable. The Federal Committee thereupon cabled £100, with a request that the chair be made in this country, and that the High

Commissioner for Australia, Sir Joseph Cook, and also Mr. Joseph Davis, formerly Director of Public Works in New South Wales, should be consulted with regard to material and emblems. Dr. Boland added that the High Commissioner and Mr. Davis had very willingly responded and made suggestions. The Council authorized a letter

to be sent to Austria conveying thanks for this welcome gift. The Presidential Chair has been carved and upholstered according to a sketch furnished by Sir Edwin Lutyens, the architect of the building. It is constructed of the Austrian wood known technically as black beech, and upholstered in red leather. The back of the chair bears, in front the Austrian coat of arms, and behind, stamped in gold lettering on a leather panel, the following inscription, in accordance with a suggestion by the Austrian Federal Committee:

BRITISH MEDICAL ASSOCIATION

PRESIDENT'S CHAIR

Presented by the Branches of the British Medical Association in Austria

to

the Parent Association in England

in token of

friendship, loyalty and goodwill,

to celebrate the Entry of the Association into its New House,

Travistock Square, London,

July, 1925

" thus which, though light as air, are as strong as links of iron

The quotation at the end of the inscription is taken from the famous speech of Edmund Burke in the House of Commons in 1775 on conciliation with America. At the reception in the Great Hall held on the evening of July 13th the chair was formally presented to the Association by Dr W. N. Robertson, C.B.E., as delegate from the Austrian Federal Committee, of which he is vice-chairman. The speeches at the presentation are reported in our account of Monday evening's ceremony (p. 146).

CONVENTION OF ENGLISH SPEAKING OPHTHALMOLOGICAL SOCIETIES

A CONVENTION of English speaking Ophthalmological Societies was held in London this week under the auspices of the Ophthalmological Society of the United Kingdom and its affiliated societies in the provinces, in Scotland, and in Ireland. A large and very representative number of members attended. On the eve of the opening of the convention some 700 names had been registered, the list included visitors from all parts of the Empire, from France, Holland, Switzerland, Austria, and China, and from the United States of America, which was represented by about 230 delegates, among whom were some of the best known in ophthalmic literature. On Monday evening, before the official opening of the convention, a reception was given by the President and Council of the Royal College of Surgeons of England. The guests, who included many ladies, were received by Sir John and Lady Bland Sutton. The whole of the museum of the College was thrown open, those sections bearing on ophthalmology, especially in the fine war collection, being particularly prominent. Members and their friends were entertained by a programme of music, and refreshments were provided in the library. The function, which was very well attended, provided a happy opportunity for introductions prior to the official opening of the convention. From mornings, three afternoons, and an evening were devoted to the scientific work of the convention, whose meetings were held in the University College buildings. During this time a heavy programme was gone through, which included two discussions, the Bowman Lecture by Sir John Parsons, and thirty-nine original papers, to which members from overseas contributed largely. The social aspect also of the meeting was well catered for: its items included a reception by the President of the convention, Mr. Tiercher Collins, a reception at the Royal Institution by its President and Council, a garden party given by Sir William and Lady Lister,

and excursions to institutions of ophthalmic interest in London, to Oxford, and to Cambridge. At University College an interesting and comprehensive museum had been prepared of drawings, instruments, and pathological and anatomical specimens, a feature of which was the number of sections illustrating much of the recent original work that has been done both in this country and in America. The official banquet which terminates the proceedings is being held in the Guildhall on Friday evening, July 17th, H.R.H. the Duke of Connaught is the guest of honour. One of the primary aims of the convention was the re-establishment of international congresses of ophthalmology on a pre-war footing. In taking the initiative in this the Ophthalmological Society of the United Kingdom is to be congratulated. The success and value of these meetings in the past, and the enthusiasm of the present convention, provide the strongest argument in favour of their continuance on the broadest possible basis.

SIR JOHN ROBERTSON MOH BIRMINGHAM

To celebrate the honours of knighthood recently conferred upon Sir John Robertson (MOH Birmingham), he and Lady Robertson were entertained at dinner on July 16th by the Midland Branch of the Society of Medical Officers of Health. There was a large attendance, and the President, Dr. R. Wolsey Stools, who was in the chair read letters of congratulation and apologies for absence from many others, including the Minister of Health (Mr. Neville Chamberlain), Sir George Newman, Professor Kenwood, Dr. Bolam (who conveyed the compliments of the Council of the British Medical Association), Professor Bostock Hill, and Professor Hope. In proposing the health of Sir John and Lady Robertson, Dr. G. F. Buchan, president-elect of the Society of Medical Officers of Health, professed congratulations on behalf of the society. He recalled Sir John's long service to Birmingham, and the singular value of his association with the university. Dr. Buchan said that he had first come under the influence of Sir John Robertson's energy and enthusiasm sixteen years ago. Research was the keynote of his policy—research for its own sake—and its practical application, this should be made the slogan of every medical officer of health, so lifting his work above politics and contemporary outside influence. Sir John had always been a great worker, and certain changes in the sphere of public health would always be intimately associated with his name: housing in relation to health, a pure food supply, especially milk, the campaign against tuberculosis, which he might be said to have initiated in Birmingham, maternal mortality, cancer research. Dr. Buchan expressed his pleasure that Sir John had been recognized and honoured during his lifetime. He had established an ideal of public health administration, and, great as he was to-day, he would appear still greater to posterity. Councillor Miss Bartlett (chairman of the Birmingham Health Committee) made a short and happy speech, paying tribute to Sir John's helpfulness and personal attributes. The toast was received with acclamation and musical honours. Sir John Robertson, in replying, spoke feelingly of the honour done to him by those gathered together that evening. His knighthood, he said, was a recognition of the public health service and of the work of medical officers of health generally, and he would carry it in their name. Public health work was happy work, though results were not immediate and could only be secured by pegging away. He had been consistently lucky all his life in being country bred, and thus early acquiring a knowledge of nature, in his masters at school, in his father, who sent him to Edinburgh, where he gained an intimate knowledge of natural history. Fiddles and music also played their part in his education, but in spite of these distractions he qualified. He was fortunate in

becoming associated with a good general practice, and regarded such experience as of the greatest value to a medical officer of health. His first appointment was at St. Helens, where he was lucky in his health committee, whose members helped in every possible way. Again at Sheffield he was no less happy, and looking back on his service in Birmingham he had no regrets. He recalled the names of Sir William Cooke, Mr. John Nettlefold (of town planning fame), Sir Ernest Hiley, and Mr. Neville Chamberlain as among those who had been greatly helpful. He closed with words of deep appreciation of the honour done to him. Mr. J. Furner Jordan, President of the Birmingham Branch of the British Medical Association, who proposed the toast of the Society of Medical Officers of Health, said that the profession as a whole was proud of the distinction conferred on Sir John Robertson. He looked upon the medical officer of health as something of a superman, for to the knowledge of the ordinary doctor he added that specialized knowledge that made him what he was. Mr. Jordan referred to the great reduction in the general mortality rate, and expressed the hope that with the more complete instruction now insisted on or in contemplation by the General Medical Council and the Central Midwives Board the perinatal mortality rate would show an equal diminution. The problem of cancer could only be solved by Sir John's method of "pegging away." Dr. R. A. Lister, President of the Society of Medical Officers of Health, responding, expressed the appreciation of the society at the honour done to Sir John Robertson, and said that it reflected on the whole public health service. The society endeavoured to secure the best and most brilliant men for preventive medicine.

ACTION OF LIVER EXTRACTS IN HIGH TENSION

The Canadian Medical Association Journal for July contains two articles relative to the action of liver extracts upon arterial hypertension. An editorial in the same issue states: "One of the papers is purely an experimental laboratory study, the other might be termed an experimental clinical study. The authors of both were associated for a period and exchanged ideas although at the time working from different hypotheses. What the ultimate benefit will be is a problem for the future, but it is gratifying to note in members of the Canadian profession not only the investigating mind but the generous co-operation with fellow workers." The shorter paper, that by A. A. James and V. B. Lughton of the University of Western Ontario Medical School describes experimental work upon rabbits, using intravenous injections of liver extracts after injection of such pressor substances as epinephrine (1 ccm of a 1 in 10,000 solution). The exact method of preparing these extracts is not stated. The authors conclude that: (1) Extracts of liver used in experimental animals effectually reduce the hypertension induced by certain pressor substances. (2) These extracts will reduce normal blood pressure to a low level (about 5 mm Hg) where it is maintained over long periods of time. (3) Large doses reduce the blood pressure to its lowest level and death ensues. (4) Preliminary work suggests strongly that the active substance is not choline or histamine. The other paper, by W. J. McDonald of St. Catharines, Ontario, accounts the results he and others who helped him obtained by injecting a solution of liver extracts into the veins of persons suffering from "essential hypertension." These results are illustrated by charts, and curves of changes induced in the normal blood pressure of rabbits are also given. The exact method of preparing the extracts is not stated. Dr. McDonald began his work by investigating the effect of liver extracts from the liver of mice acid in the blood of those suffering from carcinoma, for it had previously been shown that in such

patients there is generally a definite increase in the urea content of the blood. Later he found in one of his carcinomatous patients that injections of liver extract reduced the blood pressure so that he determined to test these extracts in a series of patients with essential hypertension. Shortly afterwards a change was made in the method of obtaining the liver extracts and Mr. W. M. McDonald, a biochemist of Hamilton, Ontario, succeeded in recovering from the extract what appeared to be the active principle in two fractions which were termed chemicals "A" and "B." Thirty-three clinical cases were studied in all, and extracts of varying dosage were injected intravenously. The usual dose seems to have been 2 ccm up to 4 ccm every two or three days. In twenty-five patients no disagreeable symptoms whatever were caused, but in another eight patients reactions followed which in varying degree resembled protein shock. In these eight cases the two chemicals "A" and "B" were combined in one injection. The age of the patients ranged from 42 to 67 years (average 61), the average duration of hypertension was six years, the average systolic blood pressure before injection 204 mm Hg, afterwards it was 142, the average diastolic pressure before treatment was 114, and this fell on the average to 86 mm Hg. Dr. McDonald states that the exact chemical nature of the liver extracts has not been ascertained, but this is being investigated in the University of Toronto. Dr. McDonald presents his results "without conclusions or deductions."

INDUSTRIAL FATIGUE

The fifth annual report of the Industrial Fatigue Research Board, which was published last month chronicles the progress of investigations covering a wide field, and includes some short papers by members of the research staff. Among subjects of inquiry having particular medical interest we note that at the request of a departmental committee appointed by the Home Secretary to consider and report upon the statutory regulations governing the use of artificial humidity in cotton factories, the Board has undertaken an inquiry into the relative incidence of sickness upon weavers in wet and dry sheds. The investigation will be carried out under the supervision of a special committee, of which Dr. Myron Greenwood is chairman and Professor I. E. Collis a member. Another research committee, of which Mr. C. J. Bond is chairman and Dr. Greenwood, Hield, Pembrey, and Pirnau members, is investigating telegraphists' cramp, and a committee, of which Dr. Leonard Hill is chairman and a majority of the members medical men, is studying the physiology of ventilation. In the last named field extensive use is being made of Dr. Hill's kymograph, a new method of measuring oscillations in air temperature by means of a delicate thermopile, invented by Mr. J. J. Manley and Dr. Vernon, is noted. It is remarkable that an increase in the oscillations of air movement has been found to cause a distinct increase of the subjective sensations of freshness, and that a simple method of increasing these oscillations, depending on intermittency in the running of the ventilating fan, has been tried. These observations may prove of much practical importance. Miss E. M. Newbold contributes an excellent paper on the pitfalls waiting the interpreter of industrial sickness statistics. She repeats the old but frequently forgotten caution that correlation does not necessarily imply causation, and culls the following excellent instances of high correlation—between the secular course of expenditure on the navy and the consumption of bananas, between ability to speak Dutch and a low rate of mortality from cancer of the breast, and between the amount of calcium in one's bone and

the number of nephews and nieces and his Miss May Smith writes on the psychological factors of industrial efficiency "It is not uncommon," she remarks, "to be told by a girl that she has nothing much wrong except that she suffers from nerves. Some employers, however, are seriously perturbed about the loss of efficiency involved in the form not only of sick leave but of inadequate work and of irritability affecting fellow workers as well. People of robust type scornfully dismiss the problem with the magic word 'hysteria,' but a label is neither soothing nor practical when the alternatives of dismissing the worker or of enduring the 'nerves' are confronted." Mr. L. Lerner contributes a very cautious note on methods of detecting liability to accidents. The report does not record any one arresting discovery but contains ample evidence of careful, routine work which is what is needed in this field.

BRITISH EMPIRE CANCER CAMPAIGN

The annual report of the Grand Council of the British Empire Cancer Campaign for the year ended May 31st, 1925, was presented at the meeting held at the House of Lords on Monday, July 13th. In his introduction the chairman, Viscount Cave, announced the receipt of subscriptions to the amount of just over £100,000. He pointed out that it has been the principal aim of the Grand Council to co-ordinate and encourage all deserving institutions and individuals engaged in cancer research work. Thanks to grants from this society, several laboratories which would otherwise have been restricted by lack of funds have been able to continue research work, and in some cases to open up new lines of investigation. Work is being carried out with radium and 2 rays under a committee appointed jointly with the Medical Research Council, £5,000 worth of radium was purchased in the early part of the year and put at the disposal of this joint committee. In addition a radon centre for the production of radium emanations was founded at the Middlesex Hospital and financed by the Campaign. The report contains a summary of the work of the various committees during the past year. The Scientific Advisory Committee meets each month to consider matters referred to it by the Preliminary Inquiry Committee and the Grand Council, together with various reports on investigations carried out at its instigation. The body of the report is taken up with statements from institutions in receipt of grants. The Cancer Research Department of the Middlesex Hospital has received £6,900, the Cancer Hospital Research Institute £5,000, the Medical Research Council (on behalf of the radon centre at Middlesex Hospital) £3,725, St. Bartholomew's Hospital £1,695, Christie Hospital, Manchester, £1,000, Tropical Disease Prevention Association £1,500, Cancer Research Laboratories of St. Mark's Hospital £600 and the Coombe Lying-in Hospital, Dublin, £200. The statement submitted by the Middlesex Hospital refers to general pathological investigations, experimental researches, diagnostic serological methods, and radiological researches. The report from the Cancer Hospital Research Institute goes very fully into the experiments Dr. Leitch and his co-workers have been carrying out on the experimental production of cancer by carcinogenic substances, as reported by Dr. Knapp in our columns a fortnight ago. Reports are submitted also on researches in clinical and surgical pathology, immunity experiments, experiments in chemotherapy, and statistical inquiries. Promising work is reported from the cancer research laboratories at St. Mark's Hospital, where a detailed investigation has been begun into the relation of simple and malignant tumours of the large intestine. Among the inquiries that are being carried out by individuals to whom grants have been made may be mentioned those of Dr. Thomas Lumsden at the Lister Institute. He is at present investigating the effects

of antisera in cancer and sarcoma, and results already obtained *in vivo* suggest that important knowledge may be gained by these researches.

THE AUTOMOBILE ASSOCIATION AND THE OFF SIDE RULE

At the twentieth annual meeting of the Automobile Association on July 8th it was announced that the membership now exceeds a quarter of a million. The annual report dealt with the activities of the association, in its parliamentary, legal, touring, and engineering departments. A paragraph of the report of interest to members of the British Medical Association is headed "Road safety—off-side rule." It is stated that the committee, after full consideration, has unanimously decided to recommend all members of the Automobile Association to adopt the "off-side rule." At present there is no standard rule for deciding at cross- and side-roads which vehicle should proceed and which should give way to other traffic. The report continues "The underlying principle of the 'off-side rule' is that every user of the street is made responsible primarily for avoiding collisions with any vehicle or person on his *right hand*. Applying this principle to cross-roads, a driver would wait for, and pass behind, any vehicle approaching from his right, and when a driver cuts in from his near side the onus would be upon him (presumably the near-side driver) to explain his reasons for so doing should an accident occur. Briefly stated, the rule means 'Watch for, and, other things being equal, give way to, traffic approaching from the right.'" The wording of the paragraph is not, perhaps, as clear as it might be, but this proposal was made many years ago by a medical motorist, Dr. Charles Buttar, whose argument was published in the *BRITISH MEDICAL JOURNAL* of February 21st, 1925 (p. 380). Later on the matter was raised at a meeting of the Metropolitan Counties Branch Council by Mr. Bishop Hayman, and again the proposal was approved unanimously. At that meeting it was suggested that the metropolitan police should be approached for the purpose of disensuring the rule in connexion with traffic regulation. It was decided to postpone acting on this suggestion and to communicate with the Automobile Association and other motoring organizations. But a joint discussion between the Automobile Association and the British Medical Association on the one hand, and the traffic authorities on the other, might well be of value, if only for the purpose of revealing any weak points in the argument. The proposed rule seems to be of sufficient value to merit such discussion.

THE ASSOCIATION'S INTELLIGENCE OFFICER

Miss A. L. LAWRENCE, who was appointed Intelligence Officer by the Council of the British Medical Association in 1919—after serving for four years on the staff of the Central Medical War Committee, for which she was awarded the M.B.E.—has lately qualified for the diploma conferring the title of LL.B. of the University of Cambridge. Miss Lawrence was Clothworkers' Scholar at Gt. St. Mary's College, 1910-14, and took honours in Part I of the Historical Tripos, 1912. In 1914 she gained first class honours in Part II, thus obtaining the Tripos Certificate which now entitles a woman to be styled B.A. Cantab. In the recent Law Tripos examination, Part II, she attained the standard for honours, this distinction, coupled with the honours previously gained in the Historical Tripos Part I, qualifies for the title of Bachelor of Laws. Miss Lawrence's colleagues, who have learnt by experience to respect her great abilities and wide acquaintance with social conditions, are glad to know that she has received these academic distinctions and feel sure that all members of the Association will join with them in congratulating her.

THE ARCHITECT OF THE ASSOCIATION'S NEW HOUSE.

SIR EDWIN LUTYENS, R.A.

SIR EDWIN LUTYENS, who designed the Association's New House, is one of the most distinguished of living architects. His works are to be found in almost every part of the British Empire. He was called in to advise the Government of India as to the laying out of the site of New Delhi; he is the architect of Government House and other buildings there, and of the great archway by which they are approached.

His name became a household word when he designed the Cenotaph in Whitehall, and he is one of the principal architects for the Imperial War Graves Commission. He has designed many war memorials both at home and overseas. At home we have from him the memorials at Leicester, Rochdale, York, Southend-on-Sea, Hove, Bury, Reading and Cuddah. He designed also the memorial of the Royal Naval Division in St. James's Park. Among the memorials overseas are those in Ceylon, Hong Kong, Bermuda, and Madras as well as British war memorials in France at St. Quentin, Itaples and Arras. He has built churches also, and as a domestic architect has been supremely successful both with exteriors and interiors. He is one of those who regard a garden, not as an excrescence but as part of the outline of the house and has given evidence of this

in the small but very perfect garden he has laid out at the south side of the South Wing of the Association's house. A very good example of his domestic style is to be seen in the small building of the Midland Bank in Piccadilly at the west corner of the courtyard of St. James's Church. To show his versatility it may be added that he has designed other business offices and also the house of the British School of Art at Rome and the picture gallery and South African war memorial at Johannesburg.

The Association's house was built before the war, but the internal decorations were never even begun; they have now been completed under his supervision, and it has been an education to watch the development of the

architect's conception through stages of apparent chaos to the final perfection. The Architectural Correspondent of the *Times* has described the exterior as "at once homely and dignified, scholarly and un-messy," and the whole building is suited to its purpose and becoming to its locality. In style, this writer continues, "it may be described as in the tradition of Wien, and slightly reminiscent of Hampton Court."

Another writer (in *Country Life*) has said of Sir Edwin Lutyens that "while the forms he uses are old he succeeds in combining them into highly original patterns. The advantage Sir Edwin Lutyens has over many of his architectural confidants is that he is content to say something new in an old language while they strain after a new language as well; this medium of expression, however, must consist of broken phrases, so their achievement has all the characteristics of immaturity." That his genius is appreciated by the members of his own profession is proved by the fact that he has received the gold medal of the Royal Institute of British Architects, and that only the other day he voyaged to America to receive the gold medal of the American Institute of Architects. He was born in 1869, was elected A.R.A. in 1913, and R.A. in 1920.

I finally, let us most gratefully say that he has shown the keenest interest in the work he has done for the Association, entering thoroughly into the special needs of its headquarters, that he gave attention to every room, conceived the bold scheme of decoration of the Great Hall, and designed the fine wrought iron screen of three gates which has been made by the Birmingham Guild and through which the King and Queen passed into the Courtyard on Monday. We will conclude by again quoting the Architectural Correspondent of the *Times*, who wrote "The best tribute to the building is to say that it is so well proportioned and so discreet in character that it gives the impression of always having been there."

Royal Opening of the New House.

HIS MAJESTY'S TRIBUTE TO THE MEDICAL PROFESSION.

THE CEREMONIES ON JULY 13TH.

WAS THE FIRST TO
HIS MAJESTY

THE New House of the British Medical Association in Tavistock Square was opened by His Majesty the King, who was accompanied by Her Majesty the Queen, on Monday afternoon, July 13th.

The opening took place with appropriate ceremonial and in the presence of perhaps the most representative gathering ever brought together in the name of British medicine. No circumstance which could give honour to the occasion was lacking. Even the one uncontrollable element, the weather, smiled upon the function, thereby relieving the minds of the organizers of their principal anxiety, for had the weather been wet the event would have been shorn of much of its spectacular effect and of a certain amount of its significance. The procession through the Court and would not have been possible, and the preliminary receptions, instead of being made at the end of the private roadway in front of the newly dedicated Gates of Honour, would have taken place in the Members' Common Room. It proved, however, to be a perfect July day, bright, but not oppressively hot—the temperature was 73° in the shade at three o'clock in the afternoon—and the red brick and white stone fittings of the New House looked then best under the blue sky, and the Gates of Honour had a particular delicacy and beauty as seen in the sunlight. The building which, with the Court, presented a scene of chaos only a few weeks or days ago, now stood finished—or at least whatever was unfinished was hidden from view—and the workmen had disappeared save for one of them who, elected for that honour by his fellows, was presented to Their Majesties. Very many of those who were present saw the New House for the first time, and expressions of admiration for one of the finest modern structures of London were heard on every hand.

The short avenue leading from Tavistock Square to the Memorial Gates was lined on each side by four Corinthian columns crowned with flowers, which gave a gay appearance to the approach. Members of the 28th London Regiment (the Artists' Rifles) formed a guard of honour under the command of Captain W. Campbell Smith, M.C. Behind them were parties of boys and girls from the Foundling Hospital for whom places had been reserved, and who greeted the Royal visitors with shrill cheers. To the south, just outside the Gates, stands had been erected for the accommodation of relatives of the members fallen in the war whose names are inscribed in the *Roll of Honour*. Some two hundred of these altogether were present at the dedication of the Memorial. In the Court and chairs were provided for about 100 members of the Association, and for representative students from every medical school in the country. By this arrangement the Court was not overcrowded, and everyone saw and heard in comfort. On the central grass plot in the centre the band of His Majesty's Grenadier Guards, by permission of Colonel B. N. Seigison Brooke, C.M.G., D.S.O., rendered a programme of music under the direction of Lieutenant G. N. Miller, L.R.A.M., and in the western ambulatory of the Great Hall a string orchestra composed of musicians from the same band also gave selections. The music, like the other proceedings, was transmitted by means of microphone and loud speakers from the Court to the Great Hall, while loud speakers outside the Great Hall enabled everybody within a big radius to hear what was going on within.

From one o'clock onwards a constant succession of motor cars entered from Tavistock Square bringing members and guests. Some of these came in academic dress or uniform, and others robed in the building on arrival. The interior of the Great Hall as it gradually filled presented a remarkable appearance. Almost every occupant of the seats in the body of the Hall wore academic costume, and the massing of the colours, scarlet predominating, toned well with Sir Edwin Lutyens's colour effects of the walls and the roof. The banners representing the cities in which Annual Meetings have been held and above these the flags of the Dominions, added to the brilliancy of the scene under the gilt steel arches. The dais, in the foreground of which two thrones had been placed, was decorated with hydangeas.

In sending out the invitations to the ceremony in the Great Hall the object had been to illustrate the solidarity of the medical profession and to bring together a representative gathering of members of the Association. Several veterans in the service and membership of the Association were present. One octogenarian was Dr. Michael Bevelley, who was secretary of the Annual Meeting of the Association at Norwich in 1874, and a member of Council for many years; another was Dr. James Stewart of Lambeth, a third who was presented to Their Majesties was Dr. G. W. Crowe of Worcester, secretary of the Jubilee Meeting held in that city (the birthplace of the Association) in 1882. Places were found for those who have held the highest offices in the Association in former years—secretaries of Annual Meetings, and former central officials of the Association. Others were present as members of the General Medical Council and the Dental Board, medical members of Parliament, representatives of universities, colleges, and medical corporations, representatives of medical and allied societies in the British Isles, the Dominions,

and foreign countries, also the heads of the Medical Departments of the Army Services. The non-medical persons present included representatives of Government departments with which the Association is frequently in contact, the High Commissioners for the Dominions, members of certain local authorities, including the City Corporation, the London County Council, the Bath City Council, and the Borough Council of St. Pancras, the borough in which the New House is situated. Certain ladies to whom the Association owes special consideration, such as Lady Horder, Mrs. Lord Trevelyan, and Mrs. G. H. Halsey, also had places assigned to them in the body of the Hall. The morning seats—some 260 in number—were filled by official representatives of Divisions and Branches in the United Kingdom, and by members of the Association who had been fortunate enough to secure places by ballot. The gallery at the south end was allotted to ladies—wives of members of the Reception Committee, of Chairmen of Standing Committees, and of other members of Council.

DEDICATION OF THE GATES

At five minutes to three the Most Reverend His Grace the Archbishop of Canterbury (Dr. Randall Davidson), who was wearing his Convocation robes and was accompanied by his chaplain, proceeded to the outer side of the Gates of Honour which were locked and a solemn but brief Service of Dedication was held.

Humphry Rolleston, Bt.) the President of the Royal College of Surgeons (Sir John Blund Sutton, Bt.), Lord Dawson of Penn, G.C.V.O., M.D., Sir George Newman, K.C.B., Sir Edwin Lutwens (the Architect of the building) and Mr. I. J. Wilton (the contractor). On the other side of the Gates other members of the Council were grouped. The embroidered gowns of the

DEDICATION OF GATES OF MEMORANCE BY THE ARCHBISHOP OF CANTERBURY.
Behind the Archbishop are standing the Architect Sir Edwin Lutwens, the Chairman of the Representative Body, Dr. H. B. Brackenbury, the Chairman of Council, Dr. R. A. Bolam, and the President of the Royal College of Physicians, Sir Humphry Rolleston.

Those standing with the Archbishop were the President of the Association (Mr. J. Basil Hall, M.Chir., F.R.C.S.), the Chairman of Council (Dr. R. A. Bolam, M.D.), the Chairman of the Representative Body (Dr. H. B. Brackenbury), the Treasurer (Mr. A. Bishop Harman, F.R.C.S.), the President of the General Medical Council (Sir Donald MacAlister, Bt.), the President of the Royal College of Physicians and Regius Professor of Physic at Cambridge (Sir

Presidents of the two Royal Colleges in particular gave a vivid touch to the scene.

The service began with the hymn, 'O God, our help in ages past,' led by the band of the Grenadier Guards.

The CHAIRMAN OF COUNCIL then, addressing the Archbishop, said:

In the name of the British Medical Association I ask Your Grace to dedicate these Gates, which have been

made and placed here in memory of the Members of our Association who laid down their lives in the Great War

Photo]

OPENING OF THE GATES

[The Times

The Archbishop, before dedicating the Gates, offered the following prayer

O God and Father of us all, Who didst send Thy Son Jesus Christ to be the Great Physician of our souls and bodies, we praise and magnify Thy Holy Name for the work of the surgeons and doctors who in the Great War saved their fellows even unto death. As in thankfulness we dedicate to thee, to Thy glory and their memory, these Gates, so we pray that all who pass through them, both coming in and going out, may also remember that it is thine not to be ministered unto but to minister. Through the same Jesus Christ our Lord. Amen

The Archbishop, advancing to the Gates, said

To the glory of God and in memory of those Members of the British Medical Association who gave their lives in the Great War, we dedicate these Gates. In the name of the Father, and of the Son, and of the Holy Ghost. Amen

Sir Edwin Lutyens, the Architect, presented the key of the Gates to His Grace, who unlocked and opened them amid an impressive silence. The Gates being open, the Archbishop said

In gratitude and hope we open the Gates. *Dominus custodiat exitum et introitum*

The ceremony concluded with the singing of "Abide with me"

ARRIVAL OF THEIR MAJESTIES

After an interval of about five minutes cheers were heard in the distance, and punctually at ten minutes past three Their Majesties drove up in semi-state in an open landau drawn by four horses and preceded by outriders. Accompanying them was the Right Hon. Neville Chamberlain M.P. (Minister of Health). A second landau contained the Dowager Countess of Minto in waiting to Her Majesty, the Lord Somers, gentleman in waiting, Major the Hon. Richard Molyneux, groom in waiting, and Captain the Hon. Alexander Hardinge, equerry and assistant private secretary. The King pleased everyone by his appearance of health and vigour. The Queen was most becomingly dressed in pale mauve, with a lace scarf, and carried a sun shade the exact colour of her dress.

Immediately on Their Majesties' arrival the Royal Standard was broken at the mast above the main entrance, and the National Anthem was played by the band of the Artists' Rifles. The Minister of Health presented to Their Majesties the President of the Association and the Chairman of Council. The King then inspected the Guard of Honour of the Artists' Rifles, and while His Majesty was so engaged the Queen occupied the President and Dr. Bolam in conversation, obviously expressing her admiration for the external appearance of the building. Dr. Bolam indicated to Her Majesty, and also to the King, who had by this time returned from the inspection of the guard of honour, the structural developments which will take place in the course of time and the extensions which will be possible. Their Majesties then came to the centre of the roadway and spent some moments regarding the newly opened Memorial gates.

The Chairman of Council then presented to the King and Queen the Chairman of the Representative Body, the Treasurer of the Association, Sir Donald

Sir Edwin Lutens, and Mr. F. J. Walton, Miss
C. M. Loris Scott, the little daughter of the Finan-
cial Secretary, betraying no more than a becoming
mount of nervousness, presented a beautiful bouquet
of Malmaison carnations and lilies to Her Majesty,
who graciously received it, and shook hands with the
young giver.

A procession then formed in the following order,

proceeding through the County and to the vaulted
passage underneath the Great Hall.

The King, escorted by the Chairman of Council.

The Queen, escorted by the President of the Association.
The Minister of Health and Ladies and Gentlemen in
attendance.

The Archbishop of Canterbury.

The Chairman of the Representative Body and the other
gentlemen who had just been presented.

[1106]

ROYAL PROCESSION THROUGH THE COURT OF HONOUR

[Topical 1108]

The procession entered the Members Common Room on the right of the passage. Here the members of the Reception Committee were assembled, and the Chairman of Council made a number of other presentations to Their Majesties. It had been intended that the first of these should be Dr F G Thomson of Bath, the President Elect, but, to the great regret of all, Dr Thomson was unable to be present owing to a severe attack of pleurisy. The following presentations were made:

- Mr C P CHILDF, F R C S, Past President (Portsmouth)
- Dame LOUISA ALDRICH BLAKE, M S, M D, Dean of the London School of Medicine for Women
- Miss FRANCIS IVENS, M S, President of the Federation of Medical Women (Liverpool)
- Dr R WALLACE HENRY, Past Chairman of the Representative Body (Leicester)
- Dr C O HAWTHORNE, Deputy Chairman of the Representative Body (London)
- Dr J A MACDONALD, LL D, Chairman of the Journal Committee (Taunton)
- Mr JENNER VERRALL, LL D, Chairman of the Dominions Committee (Leatherhead)
- Dr R LONDON DOWNS, Chairman of the Central Ethical Committee (Teddington)
- Mr H S SOUTAR, F R C S, Chairman of the Hospitals Committee (London)
- Dr H G DAIN, Chairman of the Insurance Acts Committee (Birmingham)
- Mr J B TURNER, F R C S, Chairman of the Medical-Political Committee (London)
- Mr RICHARD LUTHER KCMG MP, Chairman of the Naval and Military Committee (Derby)
- Dr S MORTON MACKENZIE, Chairman of the Organization Committee (Dorling)

- Dr T RIDLEY BAILEY, Chairman of the Public Health Committee (Bilston)
- Dr JOHN STEVENS, Chairman of the Non Panel Committee (Edinburgh)
- Dr E K LE FLEMING, Chairman of the Conference of Local Medical and Panel Committees (Wimborne)
- Mr THOMAS HORDER, Bt M D, Chairman of the Post-Graduate Committee (London)
- Mr LEWIS J MACLEAN, M D, Chairman of the Puerperal Morbidity and Mortality Committee (Cardiff)
- Dr CHARLES BUTTAR, Member of the Reception Committee (Felstead)
- Mr COMINS BERKELEY, M Ch, President of the Metropolitan Counties Branch, the largest Branch of the Association (London)
- Mr G E STAPLES, General Foreman of the Building Operations
- Mr W REYNOLDS, Elected Representative of the Workmen
- Mr DAWSON WILLIAMS, LL D, Editor of the *British Medical Journal*
- Dr ALFRED COX, Medical Secretary of the Association
- Mr L FERRIS SCOTT, F C A, Financial Secretary and Business Manager of the Association
- Mr W E HEMPSON, Solicitor of the Association

The presentations over, Their Majesties ascended the stairs to the Great Hall, which they entered from the southern end, and walked the length of the central aisle to their places on the dais. Most of those who had been already presented took their places behind them.

The company being seated, the CHAIRMAN OF COUNCIL read the following loyal Address of the British Medical Association to Their Majesties, and the KING then read the Reply, also printed in full, the whole of those present standing.

Address of the Association

MAY IT PLEASE YOUR MAJESTIES —

On behalf of the members of the British Medical Association we offer our grateful thank to Your Majesties for graciously consenting to perform the opening ceremony of the new House of the Association. We recall with pride and pleasure that His Majesty King Edward the Seventh in 1900, when Prince of Wales, graciously accepted the Honorary Membership of the Association, that on succeeding to the Throne he further honoured us by becoming Patron of the Association, and that Your Majesty did graciously consent to occupy that office on your accession to the Throne.

The British Medical Association was founded at Worcester in 1832 by Sir Charles Hastings, an eminent and public spirited physician, whose memory we desire proudly to honour on this auspicious day. The Association from its beginning has had for its objects the promotion of the medical and allied sciences and the maintenance of the honour and interests of the medical profession. In pursuance of these aims the Association has striven to maintain the great traditions of the medical profession and to interest every one of its members in the advance of the science and art of medicine, having always in mind that the members of our profession are not only guardians of the interests of the individual patients committed to their charge, but, collectively, have a duty to the community in the promotion and protection of the public health.

In its work for the advancement of medical science the Association has for many years spent about £1,000 a year on scholarships and scientific grants which have been the means of encouraging many young doctors to pursue medical research. Our Annual Meetings, at which the progress of the various branches of medicine is reviewed, give opportunities to those who have made new discoveries or evolved new ideas to place them before their colleagues for discussion, and throughout the year in the length and breadth of the land, local units of the Association carry on the education of our members and provide for them, in some measure, that post-graduate study which is so essential for progress and which we regretfully recognize has not yet been organized and developed in this country as it ought to be. In addition, the Association publishes the *BRITISH MEDICAL JOURNAL*, which is recognized as among the leading medical journals of the world, has the widest circulation of any in the British Empire, and is one of the main instruments of the Association in the instruction of its members.

Not least among the activities of the Association are those which concern the relationships of the practitioner to his fellows and to the community, and the standard of ethics rightly to be observed in a liberal profession.

From the representative character of the gathering before Your Majesties to-day it may be seen how far the Association has succeeded in its efforts to enlist the support of all sections of the profession. Among its members, anxious to serve its great objects, there have always been, from its inception to the present day, the most eminent men and women in the profession. It is all embracing in its ranks are the general practitioner—the mainstay of the Association, as he is the first line of defence on which the public relies in accident and disease—the physician, the surgeon, the specialist, the teacher, the public health officer, the laboratory worker, and in all ranks the Association has no more loyal supporters than its women members, now numbering some 2,250. May we say on their behalf how greatly we appreciate the presence to-day of Her Majesty the Queen, who has shown in so many ways her interest in the education and special work of medical women.

We would point with pride to the fact that the Association's membership is world wide, that many of our most successful Branches are in Your Majesty's Dominions over the sea, and that we are favoured on this great day in the Association's history with the presence of eminent medical representatives of Canada, Australia, New Zealand, South Africa, and India, together with many from the Colonies and Dependencies. In recent years distinguished members of the Association have officially visited South Africa, Australia, and Canada and we are assured that these delegations have played an important part in cementing the bonds of union of the profession throughout the Empire. Our relations with kindred societies in this and other countries are cordial and mutually helpful, as is shown by the presence on this occasion of representatives of almost every medical organization in this country, of representatives of several great medical associations of European countries, and of an important delegation from the American Medical Association.

Your Majesties have seen at the entrance to this House the Gates we have erected to the glorious memory of the 574 members of the Association who gave their lives for their King and Country in the Great War, and it is hoped that you will graciously inspect the *Book of Honour* in which their names have been engrossed with loving care and artistic beauty by Mr. F. G. Hallett, O.B.E. The Association records with pride that by means of its organization in local units throughout the United Kingdom it was able during the Great War to serve the State in many ways, but chiefly by ensuring the supply of doctors for the Services, having due regard to the interests of the civil population at home.

The House which we now ask Your Majesty graciously to declare open is the work of Sir Edwin Lutyens, R.A., who designed it and after its use by the military authorities during the War, has adapted it to the use of our Association. In it we shall have greatly extended opportunities for usefulness to our members to the profession of medicine and to the community at large. It will be our endeavour so to use this House and these opportunities as to be worthy of the intentions of our Founder, of the past history of the Association, and of the encouragement which Your Majesties have given us by your presence here to-day.

In asking Your Majesty to declare this House open we desire to express the loyalty of our members to Your Majesties, and to utter the fervent hope that Your Majesty may long be spared in health and strength to preside over the destinies of our great Empire.

VIEW OF GREAT HALL DURING HIS MAJESTY'S REPLY TO THE LOYAL ADDRESS OF THE ASSOCIATION

[Topical Press

His Majesty's Reply

I AM pleased to come here to day, accompanied by the Queen, to open the new and admirably designed House of the British Medical Association. We have always taken a sincere interest in the science and practice of medicine and surgery, and I am proud to have succeeded my Father, King Edward, as Patron of your Association.

Since its foundation, nearly a century ago, by Sir Charles Hastings, your Association has shown a remarkable increase both in membership and usefulness, and the well informed and constructive criticism that it brings to bear upon the evolution of your profession is of great value. The British Medical Acts wisely restrict admission to the *Medical Register* to those who have been trained in accordance with prescribed regulations and have passed the necessary qualifying examinations. At the same time vigilance must always be exercised in order that your profession may keep abreast with the advance of science, and also preserve a high standard of professional practice and ethics. The noble purpose, the character and the skill of those engaged in the art of healing, are your most precious traditions, and you do well jealously to watch over such attributes.

I am glad to notice your recognition of the advantages of post graduate study, in which my brother in law, Lord Athlone, a former Chairman of the Middlesex Hospital, has taken such a deep interest.

The reference in your Address to the ever widening scope of the medical practitioner in relation to the general health of the people is most satisfactory, and I have followed with sympathy the negotiations for securing smooth and effective co-operation between him and the public medical services. The welfare of my people at home and throughout the Empire largely depends upon an efficient and well organized health administration. The protection of maternity, the care of the child, a sanitary home and workshop, the safeguarding of the food supply, properly designed defences against infection and prevalent disease are all matters of vital importance. There is also an opportunity for the medical practitioner in his everyday practice to be a missionary and teacher of public hygiene and of personal health.

On behalf of the Queen, I thank you for your allusion to her interest in the education and work of medical women, and on this occasion we are both glad to express our appreciation of their activities in all branches of medicine.

I am especially pleased to learn of the close and friendly relations maintained between members of your profession in all parts of the Empire, and I heartily welcome here to day representatives from the Dominions beyond the Seas and also from European countries and from the American Medical Association.

At this point the King was handed by the Architect a Master Key in gold, and he concluded his reply with the words:

I have much pleasure in declaring open this House of the British Medical Association, and I congratulate its members upon the possession of their new and dignified home.

FURTHER PRESENTATIONS

The whole of the Address was heard by those in the grounds outside. The King's voice as transmitted by the loud speakers, was heard with astonishing clearness, and every syllable sounded out not only in the Court-yard but in the street beyond. Those outside the building joined with those within in the long-continued applause with which the Royal declaration that the building was open was greeted.

[Phot.]

HIS MAJESTY DECLARING THE NEW BUILDING OPEN

[Topical Press]

On the left behind the Chairman of Council is the Minister of Health. On the right behind the Queen are Sir Donald MacAlister, President of the General Medical Council, and the Chairman of the Representative Body.

Subsequently to these addresses some further presentations were made as follows:

- Dr G. W. CROWE of Worcester, one of the oldest Members of the Association who lives in the house formerly the residence of the Founder, Sir Charles Hastings
- Dr C. E. DOUGLAS, Chairman of the Scottish Committee
- Dr J. S. DAPLING, Acting Chairman of the Irish Committee
- Dr W. E. THOMAS, Chairman of the Welsh Committee.
- Dr W. A. ROBERTSON, Representative of the Australian Federal Committee
- Dr J. BANCROFT ANDERSON, Representative of the South African Committee
- Dr C. F. MACGRIPE, Representative of New Zealand
- Lieut.-Colonel L. W. C. BRADFIELD, I.M.S. Representative of the Indian Branches
- adapted to the use of the Chairman of Council of the Canadian Association
- endeavour so to use the Representative and Past President of the past history of the Association
- your presence here to day
- In asking Your Majesty to represent the Representative of France
- to Your Majesties and to u
- strength to preside over the
- Representative of Sweden
- Representative of Norway
- Representative of Denmark

INSPECTION OF THE ROLL OF HONOUR

Their Majesties, accompanied by the Archbishop of Canterbury, the Minister of Health, and the members of the Reception Committee then descended to the Library, where they inspected the Association's Roll of Honour. Mr I. G. Hallett, Secretary of the Examination Board of the Conjoint Royal Colleges, who has illuminated the Roll, was presented.

Their Majesties asked Mr Hallett how many hours he had spent on the task and were informed about 430. The King especially admired the gold work, and Mr Hallett explained that his talented assistant, Miss M. Baker, was responsible for that part of the decoration. Dr J. A. Macdonald, Chairman of the Journal Committee, then presented to Their Majesties a handsome copy of the Roll of Honour bound in purple levant morocco, and padded. The size of the pages was the same as that of the present Supplement, and every page was most carefully and beautifully reproduced by photo-mechanical means. The volume was graciously accepted and delivered into the charge of the Treasurer of the Association who undertook to convey it to the Palace.

THE LIBRARY

Mr Walter G. Spencer, M.S., F.R.C.S., the Honorary Librarian, and Mr Honcman Librarian, were also presented, and Mr Spencer pointed out to Their Majesties some of the more valuable books in the Library. The Queen showed great interest in the shelving arrangements.

In one corner of the Library Sir John Bland-Sutton, P.R.C.S., had arranged some interesting specimens which he had brought from the Museum of the Royal College of Surgeons.

The exhibits which took the King's attention most, and which Sir John Bland-Sutton explained, were the artificially shrivelled heads of three Indians from the dense forest region of the Amazon. The curious heads, contracted to perhaps one-fourth of the natural size, still had attached to them the masses of long black hair. Among other objects which caught the King's eye were the skull of a Bengalese child with a second imperfect skull attached to the anterior fontanelle, a portion of a tusk (presumably an elephant's) with a spear embedded in the pulp cavity and a layer of secondary dentine around the weapon, formed so as to wall it off from the remainder of the pulp, a human heart showing extensive laceration and loss of substance of walls of both ventricles about the apex, produced by an armour-piercing bullet used against aeroplanes, also the missile which did the mischief, a stuffed Japanese pheasant, a hen, twelve years of age, with partly assumed plumage of the male, the heart of a calf pierced by pins, thorns and twigs of witch-hazel, an example of sympathetic magic, two portions of the small intestine (probably of Napoleon I), with growth-projecting above the mucous membrane, the long blade of a bayonet which was removed from the erector spinae muscle some days after its introduction, and after the wound of entry had healed, and a complete cast of the stomach successfully removed by operation from a woman who was in the habit of eating the fibre of coco nut shells. When

he was shown a further exhibit of this kind—an immense human bill taken after death from the stomach of an alligator—the King remarked that he was familiar with the formation of these human bills. The King and Queen spent quite ten minutes over these specimens, and the King smiled at some of the zoological curiosities.

Before leaving the Library the King and Queen, using a quill pen, wrote their autographs on vellum in the Visitors Book, the signatures immediately following being those of the Minister of Health and Sir Donald MacAlister, and the Presidents of the two Royal Colleges.

VISIT TO GARDEN AND ADJOINING SCHOOL

An event which was not on the programme then took place, the King and Queen making their way through the South Wing of the building, where the Council Chamber is situated, and out into the pleasant Council Garden at the rear, with its semi-circular terrace and oval pool. In the grounds adjoining, some 120 boys and girls of the Mary Ward (Miss Humphry Ward) School in Tavistock Place, better known as the Passmore Edwards Settlement, were assembled. These are children whose physical (not mental) defects make it impossible for them to go to an ordinary elementary school, and they are brought from various parts of London in ambulances each day to receive instruction in these pleasant surroundings. Their Majesties asked many questions of the head teacher, Miss King, and spent five or ten minutes among the delighted children. Returning to the building, Their Majesties were reminded of the Dickensian associations of this particular part of the site, of which an interesting account is given elsewhere in this issue by Mr. Munhead Little.

DEPARTURE OF THEIR MAJESTIES

The King and Queen emerged from the South Wing at the western door and made their way to their carriage, which was drawn up in the Courtyard. The members of the Reception Committee and the various distinguished persons who had greeted Their Majesties on arrival assembled to give them a fitting send-off. Three hearty cheers were raised for the King, and three more for the Queen, and the National Anthem was again struck up as the procession made its way through the Gates of Honour.

Their Majesties left at five minutes past four, after a stay of fifty-five minutes.

The company in the Great Hall did not leave their places until after Their Majesties' departure. Afterwards there was a general inspection of the building and tea was taken in the Members' Common Room, while music was continued in the Courtyard and in the Great Hall for a further hour and a half.

A word should be said in praise of the police arrangements, which, under Inspector Cole, worked to perfection. Nowhere was there any crowding or jostling and the two ceremonies were carried through with entire success, thanks to the forethought of the committee in charge of the arrangements and to various officers and officials of the Association.

Acknowledgement should be made to Major E. W. Paget, C.B.E., Liaison Officer of the Home Ambulance Committee of the Order of St. John and the British Red Cross Society, for his courtesy in arranging for the provision of a detachment of nurses, who attended during the afternoon ceremonies.

Photo] [Central News
DEPARTURE OF THEIR MAJESTIES WITH THE MINISTER OF HEALTH

The following gracious message from Their Majesties was received by the Chairman of Council on the morning after the Opening Ceremony:

BUCKINGHAM PALACE

July 13th, 1925

DEAR DR. BOYD,

The King and Queen desire me to let you know what pleasure it gave Their Majesties to open the new home of the British Medical Association to-day, and to have an opportunity of inspecting this splendid building.

Their Majesties congratulate you on the excellence of all your arrangements, and thank you and all who co-operated with you for the trouble which you took to make the visit a success.

Yours sincerely,
A. H. L. HARDINGE

R. A. BOYD, Esq.,
M.D., F.R.C.P., O.B.E.

EVENING ENTERTAINMENT

PRESENTATION OF GIFTS

At night, from 8.30 to 12.30 a brilliant entertainment took place, for which invitations had been issued to one thousand guests. The grounds both the courtyard and the terraced garden behind the South Wing were illuminated with fairy electric lamps, and the House was open for inspection. Once again by means of loud speakers the whole neighbourhood shared to some extent in the festivities.

The guests were received at the top of the staircase of the South Wing leading to the Great Hall by the President and Mrs. Basil Hall. Invitations were sent to all who were present in the afternoon together with their ladies, and almost every notable person in the medical world appeared to be present. A bouquet was presented to Mrs. Basil Hall early in the proceedings. Musicians from the band of His Majesty's Grenadier Guards again gave selections, Mr. Hubert Eisdell and Mr. Harold Williams contributed songs,

and after the presentations Miss Maude Scott was permitted to sing.

Opportunity, which was not possible in the afternoon was taken for the conveyance of messages and gifts to the Association from Overseas Branches and other medical bodies.

MESSAGE TO PRESIDENT-ELECT

The PRESIDENT, before calling upon these delegates and ladies and gentlemen, I have some official duties to perform this evening, but before I enter upon them I ask you to allow me to move a vote of sympathy to Dr F. C. Thomson of Bath, who, as you know, is the President-elect, and who would have entered upon his duties as President next week. Dr Thomson, unfortunately, is suffering from pleurisy, and has telegraphed to us that it will be quite impossible for him to undertake the duties of incoming President at our Bath Meeting. I suggest therefore, that we send a vote of sympathy to him, saying how much we share his disappointment, and wishing him a speedy recovery. (Applause)

Dr BRIDGEMAN: I second the motion proposed by the President. It is, of course, a great disappointment that Dr Thomson has not been able to be with us to-day, and that he will not be with us at Bath. It must be a great disappointment to him also, but if I know anything of him I think the greatest disappointment to him will be that he has disappointed us. In these circumstances it will be a nice thing from us and a thing grateful to him if we send him a vote of sympathy, coupled with our highest hope that he will very soon recover his usual health.

The vote of sympathy was carried, and the PRESIDENT said that he would send it personally.

PRESENTATION OF DELEGATES

The PRESIDENT: My next duty is to welcome the many representatives who have come from across the seas—those from our Branches and from kindred societies throughout the civilized world. Although certain representatives of the Overseas Branches had the honour of being presented to Their Majesties this afternoon, those bring no news complete the total list of members of our great fraternity who have come across the seas to rejoice in this occasion. There are at the present moment in this room representatives of the great Dominions and of India of Ceylon, Egypt, British Guiana, the West Indies, Sierra Leone, Hong Kong and China, Mesopotamia, Natal, and Uganda. (Applause) Besides representatives of the Overseas Branches, we have with us Professor Primrose, of the Canadian Medical Association. (Applause) I have mentioned him separately, but I regard him as one of us, not only on account of our affiliation but also on account of the very kind hospitality our Canadian brethren have exhibited towards your President. (Applause) We have also representatives of the great American Medical Association. I am not sure whether Dr W. Haggard, the President has yet arrived, but we have with us Dr de Schweinitz who was President of that association in 1922-23 and Dr Howard Fox. (Applause) I can assure them that we thank them most sincerely for coming. We have also the privilege of welcoming representatives from France, Holland, Denmark, Norway, and Sweden. Norway sent to us two very welcome guests, Dr Petersen and Dr Koppang who represent the great Norwegian professional society. To each and all our guests I extend a most cordial and sincere welcome on behalf of the British Medical Association. We rejoice to have them with us and we hope that on their return they will convey to their brethren our very hearty good wishes. (Loud applause)

I will now read out a list of those Divisions which have already sent or are in course of sending a Divisional flag for the Great Hall. Some of these flags as you see have already been hung. Others are due to arrive very shortly. The Divisions are Worcester, Birmingham, Oxford, Manchester, Liverpool, York, Sheffield, Peterborough, Nottingham, Edinburgh, London, Newcastle-on-Tyne, Cardiff, Bournemouth, Carlisle, Montreal, Leicester, Toronto, Aberdeen, Glasgow and Bradford. (Applause)

The MEDICAL SECRETARY then referred to a number of messages of congratulation which had been received. One was from the Linnæan Medical Society offering sincerest

good wishes. The Académie de Médecine of Paris was unable to send a representative but added that its good wishes might be conveyed. That morning two cablegrams had come from Australia, one from the Australian Federal Committee, offering congratulations and congratulations, and the other from the Medical Journal of Australia.

CHIT OF PRESIDENT'S CHAIR FROM AUSTRALIAN BRANCHES

Dr W. N. ROBERTSON, C.B.E., Vice-Chairman of the Australian Federal Committee, said: I am very proud to have come 13,000 miles to carry the message of goodwill and affection from the Branches of the British Medical Association in Australia to the present Association at Bath. (Applause) When the Federal Committee, of which I have the privilege of being a member found that this important function was to take place they said, 'We must do something to commemorate this occasion and put up some established memorial.' We decided eventually to give the President's chair, which you now see on the platform and we wish it well and think sit upon at every meeting of the great Association here. (Loud applause) When the powers that be were good enough to cable over and invite some of us to be present to-day it unfortunately happened that Sir George Syme, who is President of our Federal Committee, was unable to come. He is presiding over a Royal Commission from which we expect great things in the way of the improvement of the health of the people of Australia. Therefore it fell to my happy lot to come over in his place. I feel very diffident about making a speech. Many and many a night I have more or less in dreams, made the most brilliant speeches for this present occasion. But as I stand here I have forgotten all those beautiful speeches. I can only express in my poor way the wonderful loyalty of the Branches of Australia. (Loud applause) We are far from you geographically, but very near you in spirit. (Applause) I come from the most distant State of all—Queensland—the most distant Branch of the British Medical Association in the world barring New Zealand. On my way here my ship called at every Australian port, and as we touched the various State capitals which are the headquarters of Branches I was made aware how strong and deep is the loyalty of Australia. They treated me like a royal envoy, not for my own sake, but because I was their messenger to you. All that wonderful kindness was then meant for me to convey to the Association at home. At Melbourne I asked Sir George Syme what I should say, and he said, "Stress the Imperial idea." That is exactly the spirit in which, in the hour of need, our boys rose up as one man to come to the help of the King and the Empire. That is the feeling which is manifest in the British Medical Association in Australia. The members of the Association out there, if I may dare to say so, are as loyal or even more loyal, to the Association than the men here at home. We are for ever loyal to this dear old parent Association which has set such glorious ideals before us. I am very proud to be here to-night, and I beg you to accept this gift from the Branches of Australia as a token of their goodwill, their affection, and their loyalty to the British Medical Association. (Loud applause)

Dr Robertson then handed over the chair, and read the inscription on the back, which is printed, together with a sketch of the chair, at pages 132-3.

The PRESIDENT, after taking his seat in the chair, said: We have yet another gift to receive from Australia, and I will reply for them both at once.

A GIFT FROM TASMANIA

Dr STODART BURN, representing Tasmania said: I have very great pleasure indeed, on behalf of the Tasmanian Branch, in offering to the President the gift of a chairman's mallet. It is a very small gift from a very small Branch, 12,000 miles away. I am privileged to be the first person to present anything to the President after he is seated in his chair. (Loud applause)

The PRESIDENT: Dr Robertson and Dr Barr, I will address you simultaneously, because there is one feature in common in both your gifts. We value them, not merely on account of their intrinsic worth, but on account of the spirit in which both have been given. It is just that sort

of spirit which binds—and I trust will always bind—the great English-speaking medical fraternity. In the presidential chair we have the emblem of dignity, in the wallet the emblem of discipline, and both must be preserved. We accept them as tokens of your very sincere goodwill towards us, and we are deeply grateful. I think we shall have to choose a rather bigger President than I am to uphold the dignity of this chair. It appears to have been arranged to seat the President and his wife. (Laughter.) We shall never forget or undervalue the spirit in which these gifts are given. (Applause.)

GREETINGS FROM SWEDEN

Dr GOTTFRID RASTEDT, representing the Swedish College of Physicians, conveyed to the Association the warmest congratulations of that body. Those for whom he spoke were sure that the scientific labours which would be carried on within the walls of the New House would be fully worthy of the brilliant traditions of British medicine. Great must be the feeling of responsibility entertained by the present generation of English physicians and surgeons when they recollect the contributions of their predecessors. Few nations could boast of such critical thinkers, such freedom from blind belief in authority. He mentioned the names of William Harvey, Thomas Sydenham, and Joseph Lister. These men and their successors had laid the whole world under a debt. Sweden had been happy more than once to confer upon British scientific men its Nobel Prize. As a slight token of admiration for the energy and scientific skill displayed in medicine as in so many other branches of learning by men of British race, he desired on behalf of the Swedish College of Physicians, the acceptance for the Association's Library of a volume containing the history of Swedish medicine during the last century. He handed the volume to the President amid applause.

The PRESIDENT said that it gave him very much pleasure to accept the volume on behalf of the Association. He deeply appreciated the spirit in which this gift and its accompanying greetings were brought.

This part of the proceedings concluded with the singing of "Auld lang syne," and three hearty cheers for the overseas brethren. Dining then began, and was kept up to a very late hour.

GUESTS OF THE ASSOCIATION

Among the many distinguished visitors present in the Great Hall during the opening ceremony, besides those whose names are printed above, were the Earl of Onslow, Chairman of the Voluntary Hospitals Commission, Sir Joseph Cook, High Commissioner for Australia, Sir Charles Sherrington, President of the Royal Society, Vice-Admiral Joseph Chambers, Medical Director-General, R.N., Lieutenant-General Sir William Leishman, Director-General, A.M.S., Air Commodore David Munro, Director of Medical Services, R.A.F., and Major-General J. B. Smith, Medical Adviser to the Secretary of State for India, Sir Archibald Garrod, Regius Professor of Medicine at Oxford, the Presidents of the Royal College of Physicians of Ireland and of the Royal Faculty of Physicians and Surgeons of Glasgow, and the Master of the Apothecaries' Society of London, the Presidents of the Royal Society of Medicine (Sir St. Clair Thomson), the Medical Society of London (Dr Callender), the Medical Psychological Association (Dr Nolan), and the Society of Medical Officers of Health (Dr Lyster). Dr W. D. Elliot, Parliamentary Under-Secretary for Health for Scotland, and the other medical members of the House of Commons, Sir Arthur Robinson, Secretary of the Ministry of Health, Sir Lisle Webb, Director-General of Medical Services, Ministry of Pensions, Sir Walter Fletcher, Secretary of the Medical Research Council, Dr E. F. Stephenson, Principal Medical Officer, Irish Free State, Professor C. J. Martin, Director of the Lister Institute, Dr C. Hubert Bond, Medical Commissioner of the Board of Control, and Dr J. G. Adams, Vice-Chancellor of the University of Liverpool, the Presidents of the British Dental Society, the Royal College of Veterinary Surgeons, the Pharmaceutical Society, and the College of Nursing. Dr Andrew Balfour, Director of the London School of Hygiene and Tropical Medicine, Brigadier-General Birkett McGill, University, Sir Lesho Mackenzie, medical member of the

Scottish Board of Health, Dr Mary Scharrlieb, President of the London School of Medicine for Women, Dr Christine Munnell, and Lady Burrett, Professor W. L. Dixon, Assessor to the Regius Professor of Physics at Cambridge, Mr George Mackay (Edinburgh), Sir John W. Moore (Dublin), Sir John Lynn-Thomas (Cardiff), Professor A. J. Hall (Sheffield), Sir Henry Crick and Sir Philip Magnus (both honorary members of the Association), Sir Charters Symonds, Treasurer of the Royal Medical Benevolent Fund, Sir Squire Sprague, Editor of the *Lancet*, Sir Holburn Waring, and Sir William Lister, the Deans of the Faculties of Medicine in the Universities, of the Medical Schools in Great Britain and Ireland, and of the Post-Graduate Colleges, together with members of Council and standing committees, official representatives of Divisions and Branches throughout the British Empire, the honorary local secretaries of past Annual Meetings, and the past and present headquarters officials of the Association in London, Edinburgh, and Dublin. The Lord Mayor of London was prevented from attending the afternoon ceremony but was present with the Lady Mayoress at the evening reception on July 13th.

ENTERTAINMENT BY THE METROPOLITAN COUNTIES BRANCH

A second entertainment took place at the New House on Tuesday evening, when the Metropolitan Counties Branch gave a reception which was even more numerously attended than the reception of the previous evening. The guests were received by Mr Comyns Berkeley, M.Chr., President of the Branch, and Mrs Berkeley. A concert was given in the Great Hall, to which Mr Hubert Lisdell (tenor) and Mr Harold Williams (baritone) contributed. This was followed by dancing to music by the band of His Majesty's Grenadier Guards. During an interval the Association prize-winners who are final-year students at medical schools within the area of the Metropolitan Counties Branch were presented with their certificates. The prizes had been awarded for essays on "The diagnosis and treatment of chronic intestinal obstruction, with illustrative cases." The prizes consisted of a cheque for £10, which had been already forwarded, and a parchment certificate which was now presented by the President of the Branch. The following students thereupon received their awards: Mr Harold Anonim (Christie Cross Hospital), Mr F. J. Immitoff (St Bartholomew's), Mr K. C. Smith (Middlesex), Mr L. Huxtable (London), Mr T. M. Ling (St Thomas's), Mr T. C. S. Webb (University College).

A number of distinguished Overseas Delegates were then presented and welcomed by the President. These were Dr P. G. Stock (South African Committee), Dr W. N. Robertson, C.B.E. (Australian Federal Committee), Dr E. G. Hutton (Grenadier Branch), Sir H. Marcus Fernando (Ceylon Branch), Professor S. W. G. Earle, M.C. (Hong-Kong and China Branch), Dr C. E. Maguire and Sir Donald McGavin (New Zealand Branch), Dr W. Milne Tough (Nyasaland Branch), Dr H. J. Holmes (Victorian Branch), and the following delegates from the Canadian Medical Association: Dr A. T. Bazin, Professor L. J. Austin, F.R.C.S., Dr H. B. Anderson, Dr F. A. G. Starr, Professor F. W. Marlow, M.D., F.R.C.S., Professor A. J. Primrose, C.B., F.R.C.S., and Dr A. D. Bickler, LL.D.

Later, in the Council Chamber, Mr E. Munhead Little, F.R.C.S., gave a short account of the historic and literary associations of the site of the New House. Mr Munhead Little's lecture appears in this number at page 111 in rather fuller detail than he delivered it. It was listened to by a large and most appreciative company. The lecture was illustrated by lantern slides, beginning with the portrait of Sir Charles Hastings, and including portraits of Dickens and other celebrities associated with the Tavistock neighbourhood. Views of the interesting houses and gardens of the locality were shown as well as a series of views of the old offices of the British Medical Association from the Great Queen Street days onwards, of which reproductions appear elsewhere in this issue.

The evening's entertainment was continued until a late hour. The great success of the function was largely due to Dr Howard Strickland, honorary secretary of the Branch, and his committee of helpers.

THE SCOTTISH BOARD OF HEALTH

ANNUAL REPORT

THE sixth annual report of the Scottish Board of Health, for the year 1924, has recently been issued. The report deals in sequence with the subjects of general hygiene, housing, tuberculosis, venereal diseases, other infectious diseases, maternity and child welfare, school health administration, supervision of food supply, national health insurance, the Poor Law, and the maintenance of aged and blind persons. In the introduction it is pointed out that, as the death rate for 1923 had been the lowest ever recorded, it was not surprising that for the year 1924 the rate had increased, the actual figure being 14.4 per 1,000. This increase was attributable, it is believed, to an epidemic of influenza which occurred in the early part of the year. It is satisfactory to note that the death rate from tuberculous diseases, and from pulmonary tuberculosis in particular, were both the lowest on record. The Board anticipates that the Milk and Dairies (Scotland) Act which comes into operation on September 1st next, will still further reduce the incidence of tuberculosis, as it will enable local authorities to control the milk supply and to effect a regular inspection of all dairy cows.

Smoke Abatement

With regard to pollution of the air by smoke, the report states that a good deal has been done during the last generation, in the Clyde Valley a decided improvement has been effected, partly through the evolution of methods of conservation and partly by means of smoke-consuming apparatus. It was agreed on all sides that there was a considerable amount of preventable pollution of the air, both by the use of small coal for the purpose of keeping down the cost of ordinary coal and also by domestic fires. It is expected that a Smoke Pollution Bill will be introduced into Parliament shortly giving powers to local authorities to make by-laws on the matter.

Disposal of Refuse

The report states that during the war the need for economy led local authorities to consider more closely whether costs could not be reduced by further utilization of waste materials and refuse, and much had been done in this respect. Reference is made to the utilization plant at Falkirk, which is providing satisfactory material in the form of screened dust for road making. Reference is made also to the fact that in Glasgow it has been decided to proceed with a large refuse disposal scheme in which electrical energy will be produced by the utilization of the heat generated from the refuse, amounting approximately to 1,000 tons a day. It is anticipated that this will result in a substantial annual revenue of £42,000, while from a plant introduced to deal with clinker it is expected that £11,000 per annum will be derived.

Housing Schemes

Attention is drawn to the important stage in housing legislation reached by the passing of the Housing Act of 1924, which contains the fifth form of Government assistance offered to aid the erection of houses. Under the various schemes of financial assistance 28,015 houses had been completed up to the end of 1924, while a total of 49,758 houses were either completed in course of erection, or immediately contemplated. This was a step towards the estimated shortage of over 180,000 houses which existed at the end of 1924. It is pointed out that during 1924 only some 4,384 houses were completed under State-aided schemes, this was far short of the desired programme of 20,000 per annum for the working classes. The building trade industry was, however, at the close of the year actively engaged in schemes for augmenting the supply of labour. The Government had set up a special committee to inquire and report on different methods of construction at present on the market. In the two previous years a fall in the cost of house building had been recorded but unfortunately, during the past year contracts have had to be placed in a market with rising prices owing chiefly to increase in the cost of labour and of certain material. With regard to slum clearance grant, thirty-four local authorities were proceeding with schemes for the improvement of insanitary

houses with the last time which the Scottish Board of Health offered them from the slum clearance grant, and the involved 6,573 reconstructed houses, of which 229 had been completed at the end of the year. The report states that a very general demand had been made by local authorities to be allowed to build a large proportion of two-part rent houses, and conference had been held on two occasions with representative of local authorities on the matter. It was decided however that in accordance with the Housing and Town Planning Act of 1919 no house of fewer than three apartments was to be erected save in exceptional circumstances. Subsequently in view of the delay that was taking place the Board had decided to relax its regulations so far as what. With regard to the provision of baths the Housing Act of 1924 had required the provision of a bath in a bathroom and in only a few cases in houses in which there was no water and drainage were multipurpose was or was not of a bath shown by the Board.

Tuberculosis

The section of the report dealing with tuberculosis is highly optimistic. It is pointed out that the death rate for pulmonary tuberculosis is at 80 per 100,000 and for pulmonary tuberculosis of 75 per 100,000 of the population in the year 1924 is the lowest yet recorded. These figures compare with only 104 and 58 respectively in the year 1914. During the decade there has been a steady decline except for a slight temporary setback during the war years. These figures show a decrease of 23 per cent in respect of pulmonary tuberculosis in ten years and a decrease of 33 per cent in non-pulmonary tuberculosis during the same period. It is pointed out that the tuberculosis movement in Scotland had its inception in the year 1887 with the institution in Edinburgh under voluntary management of the Royal Victoria Hospital for Consumption and the scheme of operations based upon it. The movement had been gradually adopted by public health authorities. By 1911 the provision for institutional treatment under tuberculosis schemes had provided 450 beds in hospitals and sanatoriums belonging to local authorities and 550 beds in voluntary institutions—a total provision equivalent to one bed per 4,622 of the population. At the end of the year 1924 there were in Scotland 111 sanatoriums, hospitals, and other residential institutions approved by the Board for the treatment of tuberculosis under the schemes by local authorities and these had provided in all 4,154 beds. In addition to these, 30 tuberculosis dispensaries had been in operation throughout the country at the end of 1924, and patients undergoing treatment at home or at a dispensary were supplied with necessary medicines and in special cases with extra nourishment at the cost of the local authority. With regard to non-pulmonary tuberculosis, local authorities are advised to relieve the pressure from general hospitals by taking over the convalescent treatment of surgical cases in sanatoriums or other suitable institutions under their control. Excellent results had been obtained also from newer methods of conservative treatment established by various local authorities. During the past few years efforts had been made by medical officers of institutions where cases of non-pulmonary tuberculosis were treated to practice heliotherapy, and lamps for the artificial production of ultra-violet rays had been installed in several sanatoriums and hospitals. General speaking the report received regarding the results from this method of treatment were very favourable, especially in the case of lupus and optic tuberculous sinuses.

Veneral Diseases

Veneral diseases centres have now been established in Glasgow (12), Edinburgh (6), Dundee (2), Aberdeen (2), Lanarkshire (6), Ayrshire (3), Fife (2) and at Stirling, Arbroath, Dumfries, Paisley, Greenock, Perth, Biff and Leith one each, to the number of 41 in all for the treatment of these diseases. The Board make suggestions for the establishment of clinics in other towns and remote areas. It is pointed out that an essential feature in each case for which a scheme had been adopted consisted in the provision of laboratory facilities, and that ten institutions had been approved in Scotland for this purpose. The question of what should be the next step in the treatment of these diseases is discussed. The report believes

that, as a number of the centres had been in operation for over six years, it might be felt that the time had come for reconsideration of the question of notification. It is pointed out that most of the bodies concerned in the matter were in favour of notification.

Other Infectious Diseases

Measles and whooping cough had been during 1924 both more prevalent and accompanied by a higher death rate in a number of Scottish towns than in 1923. The increase in cases of pneumonia (all forms) reported was very considerable, and for the whole year there were 14,698 cases as against 6,698 in 1923. In spite of the continuance of smallpox in parts of England, Scotland had remained remarkably free from this disease, and only 4 cases had been reported during the year, all being at ports. There were more cases of diphtheria in 1924 than in the previous year—4,856 as compared with 3,898—though the death rate remained constant. It had now become a regular procedure to test the staffs of various infectious diseases hospitals regarding their immunity to diphtheria by the Schell test, and in Aberdeen and Edinburgh a considerable amount of work had been done by the protective inoculation of children, both of school age and under it, against this disease. As diphtheria was most fatal amongst children between the ages of 3 and 5 years, it is pointed out that the most fruitful line of work seemed to be the immunization of children of pre-school age. Scarlet fever showed 10,809 cases in 1924, as compared with 9,504 in 1923. With regard to typhoid fever there had for many years been a very considerable fall in the death rate. During the past year several "carriers" had been discovered in mental hospitals. In the treatment of these the results of operation on the gall bladder appeared to be highly successful. In regard to acute infective jaundice, 16 cases had been reported, most of which occurred among nurses working in a wet pit of a pit where the roof slime had been found infected with leptospira, the slime being a favourable medium for its growth.

Maternity and Child Welfare

In the year 1924 the total number of births was 106,904, representing a birth rate of 21.9 per 1,000. The deaths of children under 1 year of age numbered 10,446. The infantile mortality rate was on the whole a decreasing one, but there was little indication that puerperal mortality was on the wane. Of the births in Scotland nearly 40 per cent were attended by midwives, although this did not apply to the larger towns. The effect of the measures taken against ophthalmia neonatorum was now becoming clear. Every case in which material impairment of vision occurs must be notified to the department, in 1924 twelve cases were reported to the department, and in only one of these was there complete loss of vision.

School Health Administration

With regard to school sanitation it is pointed out that the favourite school building was that known as the "central hall" type, which afforded great ease of supervision. The principles of school construction had now been entirely changed, and all new school buildings were being erected on the "pavilion" plan. The handicaps that defects of vision presented to education was very obvious, and during the past year 13,511 children were supplied with spectacles, the parents repaying, if possible, the whole or part of the cost. With regard to dental disease and treatment there was widespread evidence of awakened interest in the problem, due largely to the steady accumulation of figures in connexion with the work of school medical inspection. With regard to the prevalence of dental disease, in Edinburgh 73.5 per cent of the children were found to have decayed teeth, in Dundee 95 per cent, while Aberdeen and Glasgow occupied an intermediate position. In the counties the position was found to be scarcely less formidable, so that the total of school children in Scotland requiring urgent dental attention was about 405,000, and it is pointed out that these do not include every child with decayed teeth. To meet this there were, at the close of 1924, twenty-nine whole-time and fifty-one part-time dentists at work among the school children, the highest number employed by any one local authority being

six, in Larnarkshire, with a school population of about 101,000.

Supervision of the Food Supply

It is pointed out in the report that in regard to meat the system of inspection in Scotland had greatly improved within recent years, since the uniform standard of meat inspection was inaugurated in 1923. The Government had decided that a preventive measure of considerable importance in connexion with milk—namely, the Milk and Dairies (Scotland) Act, 1914—was to be put in operation on September 1st, 1925, while the grading of milk, for which amended regulations were issued in 1923, was now in working order and making definite progress. A departmental committee on preservatives in food issued its report last year. Its report made it plain that chemical preservatives were to be found in meat, butter, cream, margarine, sausages, bacon, potted meats, jams, mince, jellies, liquid eggs, wines, and even biscuits. The chemical preservatives in most common use were boron derivatives, sulphites, benzoates, and salicylic acid. The committee considered it undesirable that material not of the nature of food should be added to food if it could be dispensed with. Acute poisoning or possibly injury was not to be expected from the amounts of preservatives used, but there were insidious effects noticeable after prolonged use, such as dyspepsia, colic, diarrhoea, wasting, and general impairment of health. It is further pointed out that in many cases cold storage and other methods of preparing and handling food obviated the necessity for using preservatives. The committee regarded benzoates and sulphurous acid as among the least harmful of preservatives, but it recommended that if an article of food was preserved the fact should be stated on the label. During the year ten outbreaks of food poisoning had been reported, the most serious of which occurred in Dundee, and resulted in 703 persons being affected with gastro-enteritis due to the *Bacillus subtilis*.

National Health Insurance Unemployment

The annual income from this scheme from all sources amounted in Scotland to £4,200,000, and the yearly expenditure to £3,400,000. The department of National Health Insurance since 1911 is dealt with. It is stated that for the past two years a portion of the grant made to meet special needs of medical service had been utilized in enabling practitioners to take a post-graduate course of study at a medical school in cases where the nature of the practice precluded the practitioner from taking such a course unaided, and it is added that the success of this experiment had been gratifying. The valuation of approved societies and the question of proposed additional benefits are discussed. Various miscellaneous insurance questions and questions affecting insurance conditions are also treated. During 1924 there was a slight improvement in the unemployment position in Scotland as compared with the preceding two years. The average number of persons registered as unemployed for the whole year was 156,117, representing 12 per cent of the total insured population, as compared with 181,491, or almost 14 per cent, in 1923.

Welfare of the Blind

The welfare of the blind first became a function of the department in 1918, following the report in 1917 of the Departmental Committee on the Welfare of the Blind that the condition of the blind called for more active intervention by the State to secure control and assistance for the existing voluntary agencies. The Blind Persons Act, 1920, required local authorities to submit schemes for the exercise of their duty under the Act to promote the welfare of the blind. The approved schemes provided that these duties were to be carried out through the voluntary agencies for the blind. A register of blind persons was compiled and afforded valuable statistical information in regard to education, training, and employment. On April 1st, 1924, there were on the register 6,054 blind persons in Scotland, of these, 3,650 were unemployed or unemployable, but the remainder were employed or under training. Effect had been given to recommendations that technical training should be confined to that afforded by the four large institutions in Scotland which had now been recognized for the purpose by the Scottish Education Department.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

THE House of Commons this week completed the committee stage of the Widows, Orphans and Old Age Contributory Pensions Bill, discussed the Navy and devoted Friday to the concluding stages of the Summer Time Bill, to which the Government had allotted a day. The publication of a letter from the Medical Secretary of the British Medical Association officially announcing that the medical profession supported the bill was a point stressed by its advocates. In Grand Committee the Minister of Health announced concessions to the critics of the Rating and Valuation Bill which improve its chance of becoming law this year, and also the chance that the Ministry of Health will follow up rating reform by proposing next session a reform of the Poor Law.

In the House of Lords the Public Health Bill which has already passed the House of Commons was read a second time without a division.

At the House of Commons, on July 13th the Parliamentary Medical Committee was addressed by Sir William Hatcher KBE, the Secretary of the Medical Research Council, who spoke on the work the Council had initiated and its relation to other bodies. He alluded specially to the successful determination of filter passing viruses first of trench fever later of influenza, and of that associated with chicken pox. As the House divided several times during this conference discussion was brief. One member of the Committee suggested that it should endeavour to initiate a debate in the House of Commons on the work of the Medical Research Council in order to increase the interest of lay members of Parliament in medical research, but no decision was taken.

The medical members of Parliament who made the journey to Geneva have since then twice met Mr. Sprüngli at the House of Commons. At the first meeting they asked him whether he could guarantee the supply of serums and vaccines sufficient for the treatment of 100 tuberculous cases in England, the possibility of appealing to the public for financial aid to ensure the production of these remedies was also mentioned. Mr. Sprüngli asked for time to consider the question but at the second meeting between him and certain of the medical members of Parliament on July 14th no decision was reached.

Indian Medical Service

During the debate on the India Office vote Sir Richard Luce raised certain points with regard to the future of medicine in India. The Lee Commission had decided that for various reasons it was necessary in each of the provincial services to have a fixed proportion of European medical officers to carry on the work. The reasons were first that a proportion of trained European medical officers was necessary for efficiency and secondly that European members of the other services of India considered that they had a right to the services of European doctors for themselves and their families. He had experience of working very closely with eminent Indian doctors in this country who were doing excellent work but the Lee Commission stated that it was almost universally represented to be vital to have European medical officers to look after the Europeans resident in India. It was also deemed necessary to have European medical officers in the provinces to ensure a reserve for the Indian Army. Difficulties arose because the Indian Medical Service had for some considerable time been far from popular in the medical schools of this country. From being as it was from fifteen to twenty years ago one of the finest and most popular medical services of any country in the world gradually from various causes it ceased to have that popularity. Even before the war it was not attracting the best recently qualified men in England and it had been extremely difficult in the last two or three years to get enough medical men to fill vacancies. The difficulty began with the great increase in the cost of living in India and no corresponding increase in pay more than half—22 per cent—were before the war seconded for civil work and were granted the right of doing private civil practice. That had diminished to some extent before the war and in recent times had ceased to a very large extent.

It was not only the Indian Medical Service which was suffering but the Army and Navy medical services and other Imperial services had suffered from the fact that in war time relatively few qualified. Moreover India was not now so agreeable for Europeans to live in as it was in years gone by. It had only been possible to fill up vacancies in the Indian Medical Service during the last year by instituting a system of short time service under which men could go out at the end of five years with a good gratuity. That plan would be a source of welcome and expense if continued. The question arose whether the services would become still more unpopular if they were placed entirely under the Provincial Governments. He gathered that the Governor-General of India was all considering the question and Lord Curzon in his recent speech in the House of Lords indicated that it was the intention entirely to remove the control of the service from the Government and to transfer the control of the service to the Provincial Governments. If that were so the transfer might not make much difference to the popularity of the service. Sir Richard Luce went on to call attention to the

condition of the army in medical service in India. There were two separate services for troops working side by side. It seemed that a suitable time had come to introduce some method of uniting the R.A.M.C. officers and personnel who were sent out to India on a tour of duty with the Indian Medical Service which looked after the Indian Army. Many of the difficulties in the war and the scandal in Mesopotamia were out of the fact that there were dual services in India with different standards of efficiency and of equipment. There should be a united service—something on the lines of an Indian Army Medical Corps—in which the officers of the corps should be made up of Indian and British officers, and the men should consist partly of British Royal Army Medical Corps men and noncommissioned officers, attached to and united into the corps for the time they served in India, but going back when their tour of service in India was over and taking their ordinary places in the Royal Army Medical Corps. The problem was difficult but not insoluble as during the war the two services were successfully combined.

Whether the whole control of medicine in India should be passed from the State to the provinces without any reservation at all seemed a doubtful point. Medicine was a service which required control from a centre more perhaps than any other. In this country it was necessary to have control in India over such matters as education, research, quarantine and the appointment to the higher medical posts in the universities and perhaps even the hospitals. It was not safe to leave that work to so many Provincial Governments.

Earl Winterston, Under Secretary for India, in the course of his reply on the debate expressed his regret that he was not in a position to answer with regard to the medical services.

Bethlem Hospital Site.—At the Ministry of Health on July 13th representatives of the Bethlem Hospital of the Corporation of the City and of the borough of Southwark together with Dr. Halsey Guest met officials of the Ministry with regard to the bill before Parliament which proposes to authorise the transfer of the Bethlem Hospital and the sale of its present site in South London. A committee of six representing the hospital, the City and the borough of Southwark was set up in the hope that it would amicably settle the question of the disposal of the old site.

On account of the pressure of special matter in this issue we are constrained to omit some topics of medical interest which would otherwise have found a place here.

Universities and Colleges

UNIVERSITY OF LONDON

The Departmental Committee

THE London County Council is one of the bodies invited to give evidence before the departmental committee appointed to consider the final report of the Royal Commission on University Education in London and to indicate what are the principal changes which are now most needed in the existing conditions of the University and on what basis a statutory commission could be set up to frame new statutes.

The Council has expressed the view that the financial arrangements between the University and the Council should provide that the total grant fixed by the Council in aid of university education in London should be given as a block grant to the Senate while the constitution and powers of the Senate remain as at present; however the Council does not feel it possible to adopt this arrangement. It believes that the University should have a Senate in whose hands the Council could place the expenditure and distribution of any grants which it might decide to make for university education subject to any particular conditions which the Council might think it advisable to impose but it is confirmed in its attitude by the statement of the University Grants Committee that 'until the central authority of the University has become a reality it will be impossible for Parliament the London County Council and the general public to feel certain that the fullest and most economical use is made of the vast aggregation of teaching power contained in its numerous constituent bodies'. The Council has also instructed those of its members who give evidence before the departmental committee to state the Council's opinion—first expressed in 1912 when some felt that the Haldane Commission might recommend the discontinuance of the external degree—that the University of London should continue to confer external degrees.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A QUARTERLY Council was held on July 9th when the President Sir John Bland Sutton was in the chair. The successful candidates at the recent election to the Council—Mr A H Burgess (Manchester) Mr James Sheiaren (London) and Sir John Lynd Thomas (Wales) as reported in our issue of July 11th (p. 93)—were introduced to the Council.

Sir John Bland Sutton was re-elected President and Mr W G Spencer and Mr J Sheiaren were elected Vice Presidents.

Mr Graham Simpson was admitted a member of the Court of Examiners.

Licences in dental surgery were granted to 57 candidates. Diplomas were granted jointly with the Royal College of Physicians in psychological medicine to 11 candidates and in laryngology and otology to 7 candidates.

Mr T W P Lawrence was reappointed for the ensuing year to advise during the work of revision of the pathological catalogue and Mr C I Beadles was appointed pathological Curator of the Museum for the ensuing year. Mr H B Burne was re-elected Physiological Curator and Sir Frank Colver was appointed Honorary Curator of the Odontological Collection.

VACANCIES

BATH ROYAL MINERAL WATER HOSPITAL—Resident Medical Officer Salary at the rate of £130 per annum

BIRMINGHAM UNION—Resident Assistant Medical Officer at the Union Infirmary Salary £300 per annum

BIRTHS, MARRIAGES AND DEATHS

The charge for inserting announcement of Births, Marriages and Deaths is 9s. which sum should be forwarded with the notice not later than the first post on Tuesday morning in order to ensure insertion in the current issue.

BIRTHS

APPEL — At 59 Denon Road Victoria Park Manchester on July 9th to Dr. and Mrs. G. E. Archer a son.
BATHFORD — On July 5th at Cologne to Thelma wife of Captain D. T. Bathford FRCS R.M.C. a son.
BRYAN — At the Palmouth Nursing Home on July 8th last to Dr. and Mrs. H. A. Bryman of 1 Clive Place Edinboro a son.
PETER — On July 12th at a nursing home to Mary wife of Tom George Rickett of 118 Harley Street and 3 Hanover Terrace a daughter.
SCOFFER — At 13 Victoria Street Aberdeen on July 11th the wife of H. Ross Scoffer M.A. M.D. a daughter.

DEATHS

CLIFFORD — On July 8th at his residence 15 St. John Street Manchester Harold Clifford M.D. FRCS Ed. Honorary Consultant and Surgeon to St. Mary's Hospitals Manchester and the Clifford Royal Hospital.
REDDIE — On July 12th at 137 King Street Edinburgh the late Thomas younger son of Dr. and Mrs. J. E. Reddie. Interment at Pukefinch Cemetery on Wednesday at 1 o'clock.
MURPHY — On July 6th at 70 Dagger Lane West Bromwich William Maule Smith M.D. FRCS Ed. Medical Superintendent at Infirmary West Bromwich aged 51.

Medical News.

The Founder's Day celebrations of Ipswich College on July 25th will include a service in the chapel at midday, presentation of prizes by Earl Beuchamp at 2.45 p.m. and a performance of *The Midado* by the College musical society at 8 p.m.

DETAILS of the annual luncheon at Bath of the Irish Medical Schools and Graduates Association will be found in the Reception Room at the Banqueting Hall, Guildhall, Bath.

SIR ST. CLAIR THOMSON, M.D. 1 R.C.P., F.R.C.S. has been re-elected President of the Royal Society of Medicine.

The fourth Congress of Military Medicine and Pharmacy will be held at Warsaw in 1927.

The French Congress of Stomatology will be held in Paris under the presidency of M. Jules Leffler from October 19th to 24th.

The Fellowship of Medicine announces that from July 27th to August 14th there will be a five afternoon course in the diagnosis and treatment of the more common diseases of the nervous system at the West End Hospital. A vacation course will be held at the Prince of Wales's General Hospital from August 3rd to 15th, with morning and afternoon sessions from 10.30 a.m. to 5.30 p.m. devoted to demonstrations of modern clinical and laboratory methods, lectures, and the general hospital routine. The Queen Mary's Hospital, Stratford, will also hold an intensive course on similar lines from August 24th to September 5th, with special facilities for the study of gynaecology and obstetrics. Throughout the month a special course will be given at the All Saints' Hospital for Genito-Urinary Diseases with daily clinical demonstrations and a special lecture each Wednesday. Copies of each syllabus may be obtained from the Secretary at No. 1, Wimpole Street, W.1.

The London Office of the Italian State Tourist Department (12, Waterloo Place Regent Street, London, S.W.1) informs us that there are still a few vacancies in the tour arranged for British medical men in September, of which a note appeared in our issue of April 18th (p. 764). Applications should be made without delay. The party will travel by special trains in Italy and among the places to be visited are San Pellegrino, Aequi, Alatri, San Remo, Ospedaletti, Bolognara, Pogliano, Rapallo, Santa Margherita, Portofino, Viareggio, Leghorn, Montecatini, Perugia, Rome.

The Church of England Temperance Society will open in September at Caldecote Hall near Nuneaton, an institution for the study and treatment of alcoholism and drug addiction in men. In order that the treatment may be available for poor patients the society is prepared to help those unable to defray the cost. The minimum fee under this scheme will be 25s. a week. Inquiries should be addressed to the Secretary, C.E.T.S., 40 Marsham Street, Westminster, S.W.1.

The fifteenth annual report of the Mission to Lepers, founded by Mr. Wellesley C. Bailey, contains an account of the jubilee celebrations of the Mission in 1924 in different parts of the world. The yearly reports show the number of lepers under treatment in the institutions of the Mission or those aided by it to be 7,961 while 774 uninfected children of lepers are being cared for in specially provided homes. The report which is freely illustrated includes an account of recent progress in the treatment of leprosy is published at 61 and may be obtained from the editorial secretary of the Mission 33 Henrietta Street, W.C.2.

Letters, Notes, and Answers.

All communication in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**

OFFICIAL ARTICLES and LETTERS to ward 1 for publication are understood to be offered to the British Medical Journal alone and the contract is entered into with the Editor. Notice to be taken of their communication should authorise them with their names not necessarily for publication.

Authors of original ARTICLES of their articles published in the British Medical Journal must communicate with the Editor, Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1 on receipt of proofs.

All communications with reference to ADVERTISEMENTS should be sent to the Editor for copy of the Journal should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the British Medical Journal are: LONDON: 157, 158, 159, 160, and 161 (interchangeable four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR of the British Medical Journal: Antology, Westcott, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc.): Antology, Westcott, London.

MEDICAL SECRETARY: Medical Association, Westcott, London.

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams: *Bacillus Dublin*). Telephone: 1757 (Dublin) and of the Scottish Office: 6 Drumshelton, Edinburgh (telegrams: *Associate, Edinburgh*). Telephone: 4331 (Central).

QUERIES AND ANSWERS

INCOME TAX

Proportion of Income Tax Deductible

"A J" uses a portion of his residence for professional purposes and claims to deduct two-thirds of the rent as a professional expense. The Inspector of Taxes declines to allow more than one-half.

"A J" It is difficult to advise on this question because so much must depend on the exact circumstances—for example how many rooms are used mainly or solely for professional purposes whether they are on the ground floor front or elsewhere whether the rent includes large accommodation how far the rent paid is specially affected by the suitability of the premises for professional or business as distinct from residential purposes and lastly whether the balance of the rent applicable to private expenditure (one third or one half) would be a reasonable charge for the private accommodation afforded by the premises. If "A J" will send particulars on these points with a note as to the gross and net earnings of the practice we will endeavour to advise him as to whether he would have a reasonable prospect of appealing successfully from the Inspector's decision to the Commissioner of Taxes.

LETTERS, NOTES, ETC.

POWER OF ENTRY BY LOCAL AUTHORITIES

DR T. G. AARIS (MOH Greenwich) writes: I note the reply to R.P." (July 4th p. 46) respecting power of entry by local authorities. May I refer you to Sections 123 and 124 of the Housing Act, 1915 which gives wide powers with respect to entry by local authorities and their officers.

CORRECTION

Our attention has been called to a *lapsus calami* in the article on Places of Interest around Bath published in the Journal of July 11th. It is stated (p. 83) that the Cabot Tower stands on Clifton Downs. As all who are acquainted with Bristol know the tower is on Brandon Hill whence a magnificent view of the city may be obtained.

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 78, 79 and 80 of our advertisement columns and advertisements as to partnerships, assistantships and locum tenencies at pages 79 and 77. A short summary of vacant posts notified in the advertisement columns appears at page 151.

British Medical Association.

NINETY-THIRD ANNUAL MEETING, BATH, 1925.

President's Address

ON

THE EVOLUTION OF A HEALTH RESORT.

BY

F. G. THOMSON, M.A. CANTAB., M.D., M.R.C.P. LOND.,

PHYSICIAN, ROYAL UNITED HOSPITAL, BATH, CONSULTING PHYSICIAN, MINERAL WATER HOSPITAL, BATH.

Cross erected in Cross Bath to commemorate the birth of Prince James Francis Stuart (the Pretender) son of Queen Mary, of Modena.

BEFORE commencing the subject of my address, I hope you will allow me, on behalf of my colleagues and myself, to extend to all members of the British Medical Association a very hearty welcome to Bath. It is, I know, the earnest hope, not only of the members of the local Division of the Association, but of all the citizens of Bath, that this Annual Meeting may be in every way as instructive, pleasant, and generally successful as it is possible to make it.

The history of a town that has been closely associated with the treatment of disease for nearly two thousand years, and probably longer, naturally possesses many features of medical interest, and it may not be out of place to night, at the commencement of this meeting, to refer to certain phases of the evolution of Bath as a health resort, and to certain of the characters, medical and otherwise, who have played their part in its medical history.

Though the hot springs have been used in the treatment of disease ever since the Roman occupation, it was not till the middle of the sixteenth century that their therapeutic properties engaged the serious attention of the medical profession, and our knowledge of the actual practice of medicine in Bath remains very fragmentary till about the time of Queen Elizabeth, when its reputation as a resort for visiting patients first became established.

The primitive conditions, however, which obtained in the time of the late Tudors and early Stuarts were such that one imagines nothing but dire necessity would have caused anyone to visit Bath at that time. The town itself was one of the meanest in England, and the streets are said to have been a succession of dungbills, pigsties, and slaughterhouses. The baths themselves consisted of dilapidated, ill kept, dirty pools, open to the air, and surrounded only by a low parapet, over which the more idle and inquisitive of the inhabitants were accustomed to view the proceedings at their ease and leisure. Men and women bathed together, naked, at nearly all times of the day and night, and disorder of all kinds was rampant. The baths are said to have resembled a veritable bear garden, and cats, dogs, and even human bodies to have been hauled into the bath while people were bathing in it.

The complacency with which these conditions were viewed at the time is well illustrated by Harrison's account of the Cross Bath in his *Description of England in Shalpsere's*

Youth, in which he says "This bath is much frequented by such as are diseased with leprosy, pox, scabs, and great aches, yet of itself it is very temperate and pleasant." Considering the bath measured only some 19 by 20 feet, one would imagine that in the circumstances it was hardly as pleasant as Harrison suggests. Fortunately for all concerned, there was a superstition that it was highly dangerous to enter the bath for some hours before and after noon and midnight, when the water was said to "boil very ferventlie," and the baths to "punge themselves of all such filth as the diseased do leave in them"—a process which, in the circumstances, must have been highly desirable.

In spite of all the discomforts and positive dangers associated with such a procedure, Queen Anne of Denmark, the wife of James I., decided to take a course of baths in the bath known as the King's Bath. Unfortunately, Her Majesty had a somewhat alarming experience, as a ball of fire is said to have risen from her feet and spread out all over the surface of the bath. This remarkable phenomenon, which one can only suppose was an ebullition of marsh-gas rising from the mud, which was disturbed by the lady's feet, so alarmed the Queen that she refused to bathe there any more, and was with difficulty persuaded to finish her course of treatment in an adjoining bath, since known as the Queen's Bath, where she was assured such cataclysmic disturbances were never known to occur.

The reign of Charles II., however, marked the commencement of an entirely new phase in the history of the town. Whereas people had hitherto come solely for reasons of health, they now began to come for pleasure. A community which lived the gay and frivolous life associated with the

restoration of the Monarchy lost all interest in country pursuits, and when the Court left London in the summer the fashionable world preferred to migrate en masse to one or other of the provincial watering-places where the amenities of town life could still to some extent be enjoyed.

In 1663 Charles II. formally removed his Court to Bath, and the concourse of people was so great that not only the town, but the surrounding villages also, were crowded with visitors. Though certain improvements had been effected in the conduct of the baths, and

though quite a number of Bath physicians had by this time written more or less learned books on the action of the waters, the scene depicted in the print of the King's Bath in 1667 hardly suggests that balneological treatment was as yet regarded by the public with that respect which it deserved.

The proceedings appear to have been looked upon more as a popular entertainment than as a remedy for disease, and the antics of children diving for pennies, and of their elders indulging in fancy forms of swimming, appear to have afforded more amusement to the onlookers than to the

King's and Queen's Bath About 1760 (From picture by Robino)

James Francis Stuart), though born heir to the throne, was never destined to succeed to it, James II being deposed in favour of William of Orange during the ensuing year. As the Pretender, however, he was responsible for the rebellion of 1715, and his son, Prince Charles Edward, known as the Young Pretender, was the head of the much

more serious rebellion in 1745. So if no occasion had arisen for placing this cross in the Cross Bath, we should never have heard of Bonnie Prince Charlie or Flora MacDonald, and one of the most romantic pages of Scottish history would never have been written.

Long before these events took place, however, the city had reached the apex of its fame, not only as the resort of the sick and ailing, but as the periodical visiting place of all who aspired to take any position whatever in

William Oliver M.D.

the world of fashion. During the reign of Queen Anne, Bath became a sort of general casino for the whole kingdom. The Queen herself, who is said to have been such a martyr to gout that she was unable to stand during her coronation service, paid several visits, and for the next 120 years or more there is hardly a single person of distinction, from Royalty downwards, whose name is not in some way or another connected with visits to Bath, either for health or pleasure.

Thanks to the numerous authors and dramatists, such as Steele, Defoe, Goldsmith, Sheridan, Anstey, and others, who habitually visited Bath in the eighteenth century, the social habits and customs of this picturesque period are peculiarly well known to us. Whatever their other predilections may have been, we learn that the first and chief preoccupation of the majority of the company was the daily visit to the bath.

Tobias Smollett M.D.

In addition to those who took their baths under medical orders, many others bathed for diversion. The bath became a sort of fashionable parade which few cared to miss. The simple bathing dresses in vogue at the end of the seventeenth century were gradually replaced by more

elaborate costumes, till eventually both men and women took to the water arrayed in the height of fashion. Ladies of distinction bathed in state, and were attended by the daughters of prominent citizens. Those who desired them were supplied with small floating trays, on which they placed nosegays, sweetmeats, snuff, and such trifles as face powder and patches, to replace those dislodged by the moisture.

The rule that the gentlemen should remain at one side

of the bath and the ladies at the other seems to have been honoured more in the breach than in the observance. Thus Defoe, in his *Tour through Great Britain*, says:

"At the Cross Bath the ladies and gentlemen pretend to keep some distance each to their proper side but frequently mingle here too as in the King's and Queen's Bath, but not so often, and the place being narrow they converse freely and talk, rally, make vows and sometimes loves, and having thus amused themselves for an hour or two, they call their chais and return to their lodgings."

The patients were conveyed to and from the bath in sedan chais, which in the case of the ladies were, to use the words of a contemporary French writer, "hermetically sealed when the occupants were old, ugly, or prudish, but artistically penetrable when they were finely formed."

Water drinking, which by this time had become an established part of the treatment, took place later in the morning at the old Pump Room, which was replaced at the

Caleb Miller M.D. F.R.S.

end of the century by the present structure. It was here that, to the accompaniment of a prodigious amount of gossip, scandal, and general disturbance, the prototypes of Lady Teazle, Lady Candour, and Mrs. Malaprop were to be found daily, drinking their quantum of water, and at the same time unsuspectingly providing Sheridan with the material for his plays.

The general regimine and amusements of the patients, which after all constitute an important factor in their "cure," need only very brief reference. Fortunately, we are able to get some idea of them, even if it is somewhat distorted, from the caricatures of Rowlandson and other cartoonists of the period. Following the parade in the Pump Room, public breakfasts formed an important feature. Later on in the day, after promenading in the parades, or adjoining to the various coffee-houses to hear the latest news, gambling, which in the time of the Georges was an almost universal passion, occupied the attention of the majority.

Music, the drama, and art occupied the attention of the more

intellectual of the company. Concerts were held daily, and it was while singing at one of those that the beautiful Miss Linley engaged the affection of the youthful and impetuous Sheridan.

The presence of such a large number of invalids from all parts of the country naturally attracted a great many doctors, many of whom practised in Bath during the season and in London or elsewhere during the rest of the year. As

Edward Barlow M.D.

early as 1709 Steele published a jesting article in the *Tatler*, which he edited under the pseudonym of Isaac Bickerstaff, demanding that the number of doctors should be reduced. He writes

Letters have been sent to Mr Bickerstaff relating to the present state of the town of Bath, wherein the people of that place have desired him to call home the physicians. All gentlemen therefore of that profession are hereby directed to return forthwith to their places of practice, and the stage coaches are required to take them in before other passengers till there be a certificate signed by the Mayor that there are but two doctors to one patient left in the town."

Amongst all these numerous doctors there were probably a good many whose professional reputation and standard of ethics left something to be desired, and it is not surprising that in an age when wit, satire, and caricature were the predominant features in the literary world, these came in for their full share of ridicule and criticism. Thus Steele, writing in the *Guardian* a few years later, relates what he alleges to have been his own experience of the methods adopted for soliciting practice, saying

"The physicians here are very numerous, but very good natured. To these charitable gentlemen I owe that I was cured in a week's time of more distemper than I ever had in my life: they had almost killed me with their humanity. A learned fellow lodger presented me a little something on my first coming to keep up my spirits, and the next morning I was so much enlivened by another, as to have an order to bleed me for my fever. I was proffered a cure for the scurvy by a third and had a recipe for the dropsy gratis before night. In vain did I modestly decline the favours, for I was awakened early in the morning by an apothecary, who brought me a dose from one of my well-wishers. I paid him but withal told him severely that I never took physic. My landlord hereupon took me for an Italian merchant that suspected poison, but the apothecary, with more sagacity, guessed that I was certainly a physician myself."

The most bitter criticism of the local doctors comes from Smollett, the author of *Peregrine Pickle* and *Roderick Random*, both of which deal largely with the social life of Bath. Smollett himself was a doctor of medicine, and at one time essayed to practise in the town, and actually wrote a book on the external use of Bath waters. His lack of success appears to have roused feelings of intense bitterness against his more fortunate rivals, whom he describes as "a class of animals who live in the place, like so many ravens hovering round a carcass, and even ply for employment like scullers at Hungerford Stairs." In the circumstances, however, Smollett's virulent attacks on his own profession need hardly be taken too seriously, more especially as he shows a sordid tendency to paint all his characters in the most unfavourable light.

A more humorous parody on the ways of some at least of the Bath physicians of the eighteenth century is contained in Anstey's *New Bath Guide*, which, in a series of letters, relates the adventures of a somewhat unsophisticated family during a visit to Bath for the sake of their health. In a letter to his mother, written on his arrival, Mr Simpkin Blunderhead writes

"When I came here to Bath not a bit could I eat,
Tho' the man at the Bear had provided a treat
And so I went quite out of spirits to bed
With wind in my stomach and noise in my head
As we all came for health (as a body may say)
I sent for the doctor the very next day,
And the doctor was pleased tho' so short was the warning,
To come to our lodgings the very next morning,
He looked very thoughtful and grave to be sure,
And I said to myself—There's no hope of a cure
But I thought I should faint when I saw him dear mother,
Feel my pulse with one hand when I saw him dear mother,
No token of death that is heard in the night
Could ever have put me so much in a fright
Thinks I—tis all over—my sentence is past
And now he is counting how long I may last,

He determined our cases at length (God preserve us)
I'm bilious I find and the women are nervous,
Their systems relax'd and all turned topsy-turvy,
With humors, and acrid humors, and curvy
And I know the whole on, and colon
For I

So plenty of medicines each day does he send,
Pest singularis liquidas sedes sumend
Ad crepitum vesper, and man promovend
The same to continue for three weeks at least,
Before we may venture the waters to taste
And without any doubt I shall find myself stronger
When I've took the same phy for a week or two longer

He gives little Tabby a great many doses
For he says the poor creature has got the Colic
Or a rancour like so brought on the vapours
By allowing stuff she had read in the papers
And often I've marvelled she spent so much money
In Wat' Dock, I once, and half an of Honey
Such tinctures, chairs, such pills I have seen
I never could wonder her face was so green
Yet he thinks he can very soon put her to right,
With Testic I quinn that she takes every night,
And when to his spirits and strength he has brought her,
He thinks she may venture to bathe in the water."

According to Anstey, none of the doctors indulged in all baths they so freely prescribed for their patients, thus

"And to dry, many persons of rank and condition,
Were hold'd by command of an able physician
Dern Spain, Dern Manger, and Doctor Dr Squirt
Were all sent from Cambridge to rub off their dirt,
Judge Bane, and the worthy old Counsellor Pe,
Join'd I was at once and went in with the rest
And thus they all said 'twas exceedingly good
For strengthening the spirits and mending the blood.
But, what is surprising, no mortal ever view'd
Any one of the physician gentlemen stew'd
I thought many a skillful and learned phisic an
With candour, good sense, and profound erudition,
Obliges the world with the fruit of his brain,
Their nature and hidden effects to explain,
Not one of the faculty ever has try'd
The excellent waters to cure his own hide."

Though the criticisms of Steele, Smollett, and Anstey were probably thoroughly well deserved by those to whom they were directed, it must not be supposed that all the physicians in Bath were tarred with the same brush. On the contrary, many of them were men of the highest standing and repute, hardly to be distinguished, as Barbeau says, from the best of their colleagues in London. Among them may be specially mentioned Dr Hurdley, ranked by Coleridge with Milton, Newton, and Priestley, Dr Cherne, of whom Popo said there was no honester man or truer philosopher, Dr William Oliver, a founder, and the first physician to the Mineral Water Hospital, Henry Harrington, renowned for his literary ability as well as for his knowledge of medicine, William Falconer, the physician to Pitt, who shares with Priestley the distinction of being the discoverer of oxygen. Last, but not least, of the eighteenth century physicians, we have Caleb Hillier Parr, who practised in Bath from 1780 to 1816, and whose contributions to medical literature, no less than his skill in practice, entitle him to rank as one of the most eminent physicians of his day.

Though time will not allow of any references to the many distinguished Bath patients in the eighteenth century, one may specially mention John Hunter, who paid visits in 1777 and 1778 for the relief of pain associated with the aortic aneurysm, which eventually caused his death. His condition being much worse in 1785, he hastened back to Bath, but became progressively worse, and died in London some months later.

Though the vogue of Bath remained undiminished during the earlier years of the nineteenth century, important changes were gradually taking place in its fortunes, both from a social and medical point of view. Increasing facilities for travel and the wider diffusion of wealth began to lead people further afield, and Bath gradually lost its unique position as the chief, and in fact the only, resort of fashion in this country. On the medical side changes no less striking were also in progress. Balneological treatment began to be carried out on much more serious and rational lines. The promiscuous treatment of all types of patient in a common bathing pool, open to the gaze of an idle and inquisitive public, ceased with the erection, in 1798, of private suites of baths, which were the forerunners of the present installation, and in which various forms of treatment could be given to suit individual cases. The study of hydrology was being actively taken up, both in this country and on the continent of Europe.

The work of Dr Cunniff of Liverpool, and later of Priessnitz in Silesia, called attention, in the first place, to the possibilities of effective treatment by the hot and cold application of ordinary water. Side by side with this development of hydrotherapy the study of the specific therapeutic properties of the various natural waters

steadily advanced, till eventually that branch of therapeutics now known as medical hydrology may be said to have gradually emerged from a form of empiricism, based largely on tradition and superstitious belief, to a recognized branch of scientific medicine.

I think we may justly claim that the work of this Association, in stimulating the study of medicine and the allied sciences, has contributed largely to the remarkable advances made in the treatment of disease during the last century. It is interesting to note that of the eleven names mentioned of those present at the original meeting at Worcester, when the Association was first founded, two are those of Dr Edward Bailow and Mr Soden, both of Bath, who that Bath supplied no fewer than six members of the original Council of the Association. It is further recorded that at the first Annual Meeting, held in Bristol on July 19th, 1833, Dr Bailow, who became President in 1838, gave "an address of a retrospective nature", so that ninety-two years ago, almost to this day, the original members of this Association were probably listening to an address given on almost the same lines as that which I have ventured to deliver to you to night.

A Lecture

ON

SOME INVESTIGATIONS OF SENSATION.*

BY

JOHN S B STOPFORD, M.D.,

Professor of Anatomy and Dean of the Medical School,
the University of Manchester

Of all the many research workers upon sensation, none have made such valuable and extensive contributions to our knowledge as Dr Henry Head, who has not only provided us with a new vision of the loss of sensibility following division of a peripheral nerve, but has demonstrated the whole sensory pathway from the end organs to the optic thalamus and sensory cortex. By devising measurable tests and employing these for study of each individual element of sensation, he has shown that such terms as "diminished sensibility" have no meaning, and if we examine accurately the sensory disturbances in cases where such terms have been used we commonly find that one or more elements of sensation are lost and others retained. The latter information, in the light of our present knowledge of the sensory pathway, is of value and primary importance for the purposes of diagnosis and treatment.

The classical experiment upon Head's own arm constituted the crucial test of his views upon peripheral sensation and established the existence of the two systems, epicritic and protopathic, in cutaneous sensibility. There appears to be ample evidence that these two systems are independent and do not depend simply upon a modification of the same system of nerve fibres and end organs. The most striking support appears in the reverse dissociations of the two systems which were discovered in his own hand. At the periphery of the area of sensory disturbance was found a strip where epicritic sensation was lost and protopathic retained, whilst a small triangular portion was also discovered where the condition was complementary, epicritic sensation being intact and protopathic lost. In my own investigations of sensation I have encountered the same complementary dissociations of the two systems. Further proof of the existence of the two systems is to be observed during the recovery after suture of a peripheral nerve, invariably recovery of the elements constituting protopathic sensibility occurs first and most completely, while epicritic sensibility returns at a later period, and as a rule makes a less perfect recovery.

To these two systems found in cutaneous sensation Head added a third—deep sensibility—which was capable of

responding to pressure, passive movement of joints, and pain caused by excessive pressure. He found that a patient endowed solely with deep sensibility possessed not only the ability to recognize a pressure stimulus, but also the power to localize it with remarkable accuracy. Furthermore, it was decided that "the fibres subserving this form of sensation run mainly with the motor nerves, and are not destroyed by division of all the sensory nerves to the skin." Our knowledge of deep sensibility is based almost entirely upon an investigation of the residual sensation in the experiment upon Head's own arm, and less attention has been given to it than to cutaneous sensation, only scanty information proportionately being available concerning its recovery after nerve suture. It has become almost the rule in clinical work to test only one element of sensation (recognition of contact of pressure) in order to discover whether deep sensibility is disturbed, and this has probably delayed advance in our knowledge of this important division. Owing to certain observations which I made in the course of routine examinations of patients with peripheral nerve injuries, it appeared advisable to make a full investigation of deep sensibility, following the fundamental principles enunciated by Head. In the time at my disposal it is only possible to set out very briefly some of the results of this research, and I shall therefore confine myself to three aspects of the subject.

I Residual Sensation after Division of a Purely Cutaneous Nerve

Head selected the radial and musculo-cutaneous nerves for his experiments because they are described by anatomists as purely cutaneous in distribution, and his investigation was primarily concerned with cutaneous sensation. From a careful study of the sensory loss after division of the musculo-spiral or radial, I have found that the distribution exhibited in Head's hand was exceptional, and that usually the radial nerve does innervate subcutaneous tissues. This was easily demonstrated in respect of recognition of passive movement, which element of deep sensibility was clearly defective in 12 out of 14 patients suffering from division of the musculo-spiral or radial nerves. Confirmation of this observation was obtained by a study of the residual sensation in four patients with division of both the median and ulnar nerves. These and similar investigations of the sensory loss consequent upon the division of other nerves seem to make it clear that no nerve of sufficient size to be of clinical interest, or to be selected for experimental work upon sensation, is distributed exclusively to skin. This makes it almost impossible to isolate cutaneous or deep sensibility, and complicates seriously investigations upon peripheral sensation. Furthermore, it is advisable for anatomists to delete in future the misleading qualifications "purely" or "solely" of such nerves as the radial.

II Innervation of the Deep Tissues

Head's work led us to believe that the subcutaneous tissues were mainly innervated by fibres which run with the motor nerves and reached such structures as the joints by following the tendons. Such a view appears to be true if we depend for our knowledge of deep sensibility upon the results of testing the recognition of pressure alone, since we find no loss of this element of sensation after division of the median or ulnar nerves at the wrist. If we investigate all the elements of deep sensibility under such conditions we discover that deep sensibility is grossly affected. After division of the median or ulnar nerve at the wrist it is found that the recognition of passive movements of the metacarpophalangeal and interphalangeal joints of the digits supplied by the nerve is as seriously disturbed as when the nerve is divided in the forearm or arm. Measurable tests also demonstrate that the power of localization is defective in the field of distribution of the nerve under investigation. It is probable that the other two elements of deep sensibility are also dependent to a considerable extent upon branches which pass directly from the nerve trunks to the tissues. There seems to be no doubt that deep sensibility is affected seriously by division of the median or ulnar nerves in the neighbourhood of the wrist, and Dr O M Dutrie, working in the anatomy department

Abstract of a lecture given during the visit of the Inter-State Post Graduate Assembly of America to Manchester June 1925

of this university, in a study of the loss of sensation in twenty patients suffering from division of tendons (uncomplicated by any nerve lesion), has recently confirmed this observation.

III Recovery of Deep Sensibility

From the study of the recovery of the deep sensibility after nerve suture in a large number of patients it has become evident that deep and cutaneous sensations are strikingly comparable. Just as Head found two stages in the recovery of cutaneous sensation, two similar ones have been found in the study of deep sensation. Two elements of deep sensibility (recognition of contact and pressure pain) recover early and very completely, as a rule during the stage of protopathic recovery, while the other two elements (localization of pressure and recognition of passive movement) recover later and less perfectly, as in the case of epicritic sensation.

When we notice the elements of sensation in both cutaneous and deep sensibility, which recover early and late, in connexion with Head's researches on the sensory cortex, we seem to get some light upon the problem as to why two stages in recovery are found. It has been suggested that protopathic sensibility recovers earlier than epicritic because the former is more primitive and regenerates at a more rapid rate. Such an explanation supposes some structural difference in the two systems, but Adrian has shown that it is highly improbable that there is any definite structural difference in the fibres concerned with protopathic and epicritic sensation. A simpler and more effective explanation is suggested when we take into consideration all the forms of sensation, in both skin and the subcutaneous tissues, which return during the later stage of recovery. The forms appearing late, and which more frequently exhibit imperfect recovery, are those which Head has proved to have cortical representation, while the forms which recover early and more completely and constantly are those which may be expected to persist after destruction of the sensory cortex. Therefore it appears more reasonable to discover an explanation of the two stages of recovery in the central nervous system, rather than to find it due to a different rate of regeneration of two sets of fibres which anatomically appear to be identical. After suture and regeneration of a peripheral nerve a much longer period must be expected to elapse before the fibres subserving cortical forms of sensation function correctly than in the case of the fibres conducting thalamic aspects of sensation, since a very much more complex readjustment and reeducation is necessary after regeneration in the former case than in the latter. This central explanation of the two stages in recovery also offers obvious reasons for the more perfect and complete recovery after nerve suture, of those elements of sensation which have thalamic representation.

Summary

To summarize the more important results of these investigations of deep sensibility, I would suggest

1 No nerve of sufficient size to be of clinical interest is distributed solely to skin, and in consequence it is practically impossible to isolate cutaneous and deep sensibility.

2 The principal innervation of the deep tissues is by nerve fibres which arise from the main nerve trunks and pass directly to the end-organs. The supply by fibres which accompany the motor branches and pass to their final distribution along tendons seems to be only supplementary.

3 It is necessary to divide deep sensibility into two systems, comparable to Head's subdivision of cutaneous sensation. Recognition of the contact of pressure and the appreciation of pressure pain recover early, while the recognition of passive movement of joints and the localization of a pressure stimulus recover late and less perfectly.

4 A more satisfactory explanation of the reason for the two stages of recovery in both cutaneous and deep sensibility is to be found in the central nervous system, from a study of those forms of sensation which are dependent upon the sensory cortex and the thalamus.

5 For a classification of the elements of sensation affected by division of a peripheral nerve the following scheme may prove serviceable.

I Cutaneous Sensibility

Thalamic (early recovery)—Discrimination of wider differences of temperature. Cutaneous pain.

Cortical (late and less perfect recovery)—Appreciation of minute forms of touch. Localization of light forms of touch. Discrimination of finer differences of temperature. Recognition of a compass point, etc. ultimately applied, as to.

II Deep Sensibility

Thalamic (early recovery)—Appreciation of contact of pressure. Pressure pain.

Cortical (late and less perfect recovery)—Recognition of passive movement of a joint. Localization of pressure.

A British Medical Association Lecture

ON

THE NERVOUS CHILD AS SEEN IN MEDICAL PRACTICE.*

BY

BIRNARD MALLS, C.M.G., M.D., M.R.C.P.,
PHYSICIAN TO INFANTS IN THE FOYAL WATELOO HOSPITAL

The nervous child may be defined as one who is capable of intense emotions which can be quickly aroused and over which he has insufficient control. His nervous system is unstable. This is made very manifest in sickness, and certain symptoms thus noticed may long act as a reminder. Guthrie states that individual instability may be shown in defective control of the lower nerve centres by the higher.

There are two types of the nervous child, which were called by Leonard Guthrie (1) the unrestrained emotional type, and (2) the restrained emotional type.

In the first type the child is as a rule thin and of slight build. The face is not infrequently pale, yellow complexioned, and dark lines may be visible beneath the eyes. Cameron has called attention to the nervous steeple which so many of these children adopt, in which the abdomen is very prominent, the shoulders thrown well back and the head slightly forward, lordosis is not infrequent, and winging of the scapulae is sometimes seen.

Although the nervous child appears to be a mass of animation and is possessed of restless energy, he tires easily. The vasomotor nervous system would seem to be a source of trouble in many cases, as instanced by the dusky looking hands and feet, and sometimes chilblains or even Raynaud's disease, and the quick changes of colour which may occur in the cheeks and lips. Tachycardia, precordial pain, tachycardia of a functional nature, abdominal pains, mucous diarrhoea, constipation, headache, and migraine, may be all due to vasomotor disturbance. Hyper-sensitiveness of taste, hearing, sight, smell, and touch are usually present, and especially the last named. No wonder that as babies they are difficult to feed. The intelligence may be normal or above, but occasionally it is below the normal average.

The nervous child is filled with restless energy, but unfortunately determination is not commensurate with his energy, and it is not difficult for him to be discouraged from his purpose. Difficulties seem to him to be greater than they really are. He may often enter into things with enthusiasm if the impulse so moves him, but he works with almost fierce energy for a short period and is only too ready upon the least feeling of exhaustion to leave his purpose uncompleted. It is strange, but this child, so often clever, is apt to be rather amiss in judgement and common sense. Trifles worry him, and yet he does not always appear to have it in him to do what is necessary to overcome the difficulties which cross his path. The child is generally timid, and in the majority of cases he will not protect himself if attacked by another child. Nearly every neurotic child is imaginative, fearful of trouble, and rather apt to believe in that which is superstitious. Many

Abstract of a lecture delivered to the Bournemouth Division of the British Medical Association on December 17th 1924.

The first raids were made between 8 and 9 years. In several cases the children were first terrified by screaming fits, frightful night terrors, sleeplessness, and unduly afraid of animals.

Of the 82 children whose symptoms were noted on the special nervous forms the following points were observed: Excitable 77, frightful 69, cried easily 63, timid 49, shy 48, emotional 63, sensitive to scoldings 73, dainty ways 43, considered delicate 34, dark lines under eyes 48, love of sympathy 47, impressionable 56, imitative 42, weak will power 14, jealous of the baby 16, likes to be the centre of attraction 41, love of attracting attention 44, egoism 25, ungovernable temper 31, stubborn 42, likes liberty of action 65, appears anemic 24, appetite *plus* 35, appetite *minus* 47, constipation 22, diarrhoea 7, vomiting 10, sucking difficulty (babies) 2, gastric pain and discomfort 32, grimaces and habit spasms 30, arithmomania 16, twitching and convulsions 17, spasmodic 5, stammering 7, thumb sucking 7, nail biting 29, nervous cough 25, feverish attacks 34, rheumatism 24, faintness 12, cardiac irregularity 5, fatigued easily 40, flushing and blushing 49, restless at night 53, dreams 53, teeth grinding 42, night terrors 39, day terrors 6, somnambulism 14, enuresis 14, afraid of people 11, fear of being animals 29, afraid of horses 28, afraid of the dark 39, afraid of alone 37, learns easily 61, slow intelligence 15, pica 3, katatonia 3, hysteria 1, nervous stance 3 (it is probable that the nervous stance is more frequent than stated here), air-swallowers 6, No tongue-chewing thigh friction etc. or stigmata of degeneration were noted in a certain number but the mothers are likely to be present in some of these things. Negativism is a prominent feature in some of these children.

Examination of the

In the medical

Examination of the Nervous Child

Examination of the Nervous Child

In the medical examination of the nervous child it is advisable for the doctor to make a point of taking as little obvious notice of the child as possible, although he should closely scan the little patient to observe the smallest points of interest. If the child thinks that he is being made the subject of a close investigation he is apt to become an obstructionist, cry, or go off into a fit of temper. The more he is ignored the more natural he will

be and the more easy the examination becomes, therefore the more that can be learnt. A few explanatory words to the mother beforehand will be sufficient for her to understand the method of procedure. This method also teaches the mother in object lesson in that she will see that instead of promising the child a chocolate or some treat for being good the child is simply ignored, promised nothing, and expected to be good because it is his duty to be so. Nothing should be said in front of him except that which is desirable and mentioned on purpose for his edification. The real talk to the mother should proceed only when the child is taken out of earshot by the nurse.

In Sickness

Probably no child is a greater source of trial to medical men than the nervous one in sickness. If unrestricted and always given in to his will, unless severely ill or too weak to make himself heard, indulge in the antics of the pronounced obstructionist. Things will not be made easier if the mother or nurse has been in the habit of stringing the child at not infrequent intervals that should it not do as it has been told she will send for the doctor. It is a matter of great importance to enter the sick room of a nervous child without taking any special notice of him and quietly and gradually proceed to examine his organs while ignoring any protests which may be manifested, as if the child was really not in any degree refractory. One can definitely state that this method practically always succeeds.

Some nervous children get active delirium upon any marked rise of temperature. No prescription should be written to please the mother because she is overanxious. Such a matter needs a little sound common sense talk from the doctor as to the method of procedure. Whether a nervous child be well or sick it can be made to do almost anything and submit to treatment if it be represented to him as a game and a privilege. If a nervous child be seriously ill he will readily enough submit to treatment. No matter how often a nervous child may have slight illnesses or pyrexia, it is necessary to exclude every likely possibility whenever he is sick, lest the cry of wolf be made once too often.

In the nursing of such a child it is wise to have a nurse who is a stranger and not one of the family. She should be a well-bred and regenerated member of a quiet democratic, upper middle class family with a good, trained, sensible children's nurse of middle age, quick understanding, and common sense, a sufficiency of determination interwoven with firmness, sportsmanship, and absolute self-control. The lesson taught by such a nurse bears good fruit and augurs well for the future if the same method be persevered in after recovery.

At School

The question often arises, Should the nervous child be sent to school? and unless the child in some way be mentally affected, physically unfit, or if a suitable school be not available, I think the answer should always be yes. Where a suitable school, schoolmaster (or schoolmistress in the case of girls), and staff are available there is no question that the nervous child is much better off there. He should be sent as a boarder at the age of about 8 to 10 years. He needs plenty of fresh air, hygienic surroundings, good light to read by, a sufficiency of exercise without being allowed to become exhausted, adequate sleep, not too much mental work, but the usual amount is generally well within his powers as he works quietly. It is necessary that he have a sufficiency of good food, which he must be taught to eat slowly and not to bolt, and, perhaps one of the most important things of all—suitable manly boys in the one case, and fine sensible quiet type of girls in the other. Undesirable companions must be kept away from this type of child as he is so impressionable, more especially when he is reaching the age of puberty. Well trained, with a little encouragement and with the knowledge that he can approach the schoolmaster for a heart-to-heart talk whenever it seems desirable, such a child can be made into a fine creditable specimen and gain that self-control which is essential to the evolution of the manly boy or the sensible, mentally balanced girl.

Defects of sight and hearing, should be efficiently treated, the memory should not be overtaxed nor the mind bored by too much of one subject. Children probably learn with little effort those subjects for which they have talent, but nervous children should not be allowed to work for too long at a time. Indeed, these children should neither be encouraged nor allowed to overwork. Mental overstrain may be accentuated by overwork, failure with its disappointments, or apprehension of failure. Ambition thwarted may also lay bare undesirable traits, such as hatred and jealousy of rivals. There may be severe headache which would require treatment.

He learns "to play the game" at school, to speak the truth fearlessly, to be absolutely honest, to perform services for others, to play for his side and school and forget his own interests when they are opposed to those of the school, self-sacrifice, manliness, self-control, and *esprit de corps*. No child needs more to learn "the other man's point of view" and all these wholesome lessons than the neurotic child. The games, the outdoor life, the boy's excursions, and good companionship will make a man of him. Neurotic girls can safely be sent to a suitable boarding school at the age of 12 to 14 years. Previous to this arrangement it is wise in some cases for the girl to go to a day school, more especially where the Montessori system obtains and in others to have a governess of the right type at home.

General Lines of Treatment

We must keep in mind here that wherever we cannot change the neurotic disposition of the nervous child for a placid one, we can teach the child self-control. As the mother is practically always neurotic, she should carry out self-control upon herself in order that her child, full of imagination, and very impressionable, may copy from her that absolute requisite—self-control. Should the environment be impossible, it is wise either to place the child under a suitable nurse or person in the home, or send the child away to a relative or friend in the country who possesses the necessary qualities to bring him up. Later on a suitable school is selected to carry on the good work.

Corporal punishment is not likely to be successful in the case of neurotic children, as they are sensitive, impressionable, and often very aware of their own peculiarities or shortcomings, gentler ways are conducive to much greater success, and save much heart-breaking. Confidential chats with the right person and good example are much more beneficial. Let us repeat here that suitable companionship is essential in order to produce the best effect, an undesirable companion to a neurotic boy or girl spells great danger.

During infancy a neurotic baby is apt to be awkward in taking the breast. He should be handled little, kept quiet in a room without a too strong light in it, and encouraged to sleep peacefully in a warm cot free from draughts, from whence he should be brought to the breast before he is fully awake. Digestive difficulties are apt to appear early, as their taste is very sensitive, and therefore much caution and care are required to get and keep the infant on breast milk, and, failing that, on a milk mixture which does not vary in taste. It is best to accustom nervous babies from the first to an exact well regulated routine if possible. For sleep the room should be made dark and the cot warm. Quietness is essential. I am convinced that from a very early age a baby takes its cue from its mother's face as to who is to be master. It must not be the baby.

After 2 years of age discipline is essential, and is chiefly attained by good example, fairness, firmness, honesty, sportsmanship, and understanding. We bring up and educate our children with the intention of making them worthy citizens, and in time good husbands and wives, fathers and mothers. In this we must fail to a certain extent, for by no means all fathers and mothers, perhaps especially the latter, are fit to bring up their children. We do not desire the severe discipline dear to our grandparents, nor the laxity and sporting too frequent to day. It is well not to be always on the outlook for faults, better sometimes to pretend not to see them. These children should always be taken quietly and without getting angry, or they will be only too apt to lose respect for their instructors, even if they be the parents. Commence the right methods early,

so as not to lose the most impressionable time of their lives. Should you have to break your promise to a child tell him frankly the reasons which made it necessary, and he will understand and appreciate the confidence. Never give away or scold a nervous child in public, always have heart-to-heart talks when no one else is present. A little encouragement is essential, and credit for good qualities should be given wisely.

Mens sana in corpore sano is a motto specially suited to the nervous child, for generally speaking the fine physical condition of the athlete is a help to the building up of a well trained mind upon which to inculcate that priceless quality most necessary to the neurotic child—self-control. On such a child it will not be difficult to impress moral lessons and good example.

Every child should be instructed in the meaning of sex so that the subject is learned in a clean and wholesome manner from the parent and not picked up in an objectionable form from another child or other source. The great danger is ignorance and pollution. The subject should be gently approached and shown by biological references to be one of the utmost purity. A beginning will probably be made at about the age of 8, the subject will again be referred to occasionally from time to time, and then if at puberty high ideals and good example be shown there will be little likelihood of foul thoughts, masturbation, and other objectionable things worrying the child. It is the neurotic that particularly needs instruction and example.

There can be no doubt that infinite harm resulted from the one-time popular methods of placing neurotic children in a dark room, in which they were semi-starved, threatened, shouted at, and whipped. Such methods were barbarous.

Treatment of Certain Conditions

In treating vasomotor symptoms potassium bromide and streptamine are invaluable, especially for headache. Sometimes it is advisable to add small doses of liquor arsenicalis. For an actual attack of migraine a dark room, quietness, and phenazonum or aspirin are invaluable. Tics should be treated by creating a quiet environment, pretending not to notice the movements unless occasionally in a kindly way, and the administration of bromides and valerian. Any source of worry should be removed. Tonsils and adenoids needing treatment should be attended to at once.

Sleep.—Many nervous children are light sleepers. They may be restless on going to bed, and the activity of their brains is only too apt to prevent deep sleep. Avoidance, as far as possible, of disturbing and distressing scenes during the day, more especially the latter part, the carrying out of a healthy regime, a well ventilated night nursery with dull dark blue walls, are things of importance. Everything should be done to prevent mental worries or torments occurring during the day at school or at home. The child must be taught to forget himself in the street and learn to observe closely and be interested in his immediate environment. It may be advisable to remove him from school for a week or two. The child ought to be quietly put to bed at night in a night nursery with the window partly open, and at least two hours after tea. This should consist of digestible food only. Nothing tight must be placed around him, and sufficient but not too much clothing over him. If a night-light can be done without all the better. Holding the child's hands while it goes to sleep is not called for and is a waste of time. No one should stay in the room with him, but he should be aware that someone is in an adjoining room. If a child should dream or have night terrors a soothing hand placed on the child and a few words of assurance should be wakened up will tranquillize his mind, and he will soon fall asleep again. Sometimes a dose of bromide is advisable at bedtime for a few nights.

Somnambulism occurs in an appreciable number of neurotic children. The food, the bowels, the daily routine need inquiring into and adjusting if necessary. It may be advisable to tie a bandage or cord to a belt secured at the back of the child, the cord being then fastened to the foot of the bed.

Anorexia nervosa is quite easily cured if the right person adopts the right methods. The child often acts the part, and knows that by refusing food it causes consternation to his mother and nurse, if satisfaction to himself. It is advisable for the mother or nurse to speak to the child alone and agree to have "a secret" with him, by which "he is to eat as much as he can at every meal for a whole week and give everyone a surprise." He loves the secret and the performance of something which will call forth surprise and praise at his achievement. Once successful, he feels that he must live up to his new reputation. If for some reason success is not realized, it is well to arrange for the child to be removed to a suitable nursing home with the right nurse in charge of him. Digestible food should be daintily served. The mother will be surprised at the good result.

High Temperatures.—These may be due to a serious condition, a slight one, or to no discoverable cause. The last mentioned is not infrequent, but in a number of such cases slight tonsillitis is present. Pylitis, otitis media, throat affections, chest trouble, an oncoming illness, etc., must always be first excluded. Causeless temperatures are likely to recur. They can be treated by rest in bed, milk of magnesia, and small doses of bromide and salicylate.

Mental and physical fatigue are easily produced but soon recovered from after a short period of rest, when once again the child feels full of energy. As little as possible should be made of this in his presence, or indeed of any symptoms from which the child may suffer.

Enuresis.—Before treating as neurotic it is necessary to eliminate all other likely causes, such as diabetes mellitus or insipidus, chronic interstitial nephritis, pyelitis, affections of the bladder and urethra, epilepsy, drinking too much water, worms, endocrine deficiency, certain diseases of the nervous system, etc. The urine should always be carefully analysed and microscopically examined. Should the enuresis be due to the neurotic condition of the child the following procedure is useful irrespective of whether or no drug treatment be adopted. Suppose a child is passing urine at half-hour intervals during the day, he should be encouraged to hold his urine for longer periods, at first for three-quarters of an hour, then one hour, gradually lengthened until the intervals reach two to three hours. The bladder will become accustomed to retain urine for longer periods, and the habit of nocturnal enuresis will be greatly lessened. In addition, it is a good plan for the child to repeat to himself deliberately three times immediately after saying his prayers "Willie (or Mary)—will—not—wet—the—bed—to-night." Whether the child gains confidence from this or an effect is produced on the higher controlling centre over the lower I do not know, but it is certainly often successful. Scolding is harmful and encouragement most helpful. It is well considerably to restrict the amount of fluids drunk after tea. Waking up the child to pass urine half an hour before the accident occurs is often a useful procedure for a week or two. Obviously any abnormal condition present would receive appropriate treatment.

Headache and Migraine.—Every likely cause, such as errors of refraction, enlarged tonsils and adenoids, constipation, etc., must first be looked for and, if present, treated. Then the environment, school conditions, and daily routine need careful consideration, and must, if necessary, be regulated to suit the case. For a bad attack bromide or phenazonum with rest in a quiet darkened room is a valuable procedure.

Finally, let us bear in mind again that we desire to bring up our neurotic children in such a way that their best and most desirable qualities are accentuated in order to obtain the results conducive to success in life, while eliminating, diminishing, or keeping in check undesirable traits. Once a neurotic probably always a neurotic, but when the neurotic child has obtained full self-control not much fear need be entertained in the vast majority of cases as to his future. Hence the tremendous responsibility of parents, guardians, and schoolmasters.

During the late war a certain British general, after talking to an officer in charge of a battery of artillery, walked away to a spot about 150 yards distant. As soon as he

arrived there a shell fell at the feet of the artillery officer, literally blowing him to pieces. So great was the immediate shock produced on the general that he felt an almost overwhelming desire to bolt for his life. His nerve had completely left him for the moment. However, it so happened that he had been brought up from early childhood to have complete control of himself. It then flashed through his mind that, if he acted according to his first impulse, he would suffer severely from shell shock and be of no further use during the war. He therefore determined to remain, and, pulling himself together, quietly walked over to the spot where he and his brother officer had stood a few minutes previously. He stood at attention for five minutes, regained his nerve, and fought to the end of the war without suffering from shell shock. It is this self control and sense of duty which we must endeavour to inculcate into every nervous child.

THE INCIDENCE OF ARTERIO-SCLEROSIS IN THE ARTERIES OF THE BODY

BY

D. RUTHERFORD DOW, M.D.

(From the Department of Anatomy, University of St. Andrews)

THE following investigation was undertaken to ascertain which vessels in the body were most frequently and most extensively affected with arterial degeneration. The material examined was obtained from the dissecting rooms in the University of St. Andrews. The bodies were in an excellent state of preservation, and each was over 50 years of age. The method adopted was to dissect the arteries free from surrounding tissues, and to make a naked eye examination in both longitudinal and transverse section. It is not possible to conduct an examination of this nature in the post-mortem room. Complete records of the incidence of arterio-sclerosis have not hitherto been published from dissecting rooms.

The pathological changes of which I took note were hardness and thickness of the vessel wall, the result of fatty or calcareous degeneration, a state which rendered the artery less capable of performing its proper functions.

With the naked eye there were seen projections of the inner coat, oval or circular, of a more opaque or yellow colour than the surrounding tissue. The patches, which were sometimes raised, varied in size from a hempseed to a shilling. In a few of the vessels the earliest naked eye change was linear streaking. In many the intima was quite smooth, but on peeling it off a thickening of the media (with calcareous degeneration) was found. I did not make any distinction between sclerosis which commenced in the media or intima, as the established disease in either coat was almost invariably associated with secondary changes in the other. The changes which I took note of were observed by inspection and palpation, and included arterial decay of any form and from any cause.

Rokitansky and Lobstein, Thoma, Bellinger, and Clifford Allbutt have all conducted a similar investigation, but for certain reasons a complete examination of the body was not carried out. Clifford Allbutt reported, in his *System of Medicine*, that he examined 1,600 cases in the post-mortem rooms of Charing Cross Hospital, but only 380 were found to exhibit arterio-sclerosis, but then, "for some reason or other in 1,200 complete examination was not made."

I carefully made a naked eye examination of all the arteries in eight bodies with the following results:

ABDOMEN

The Abdominal Aorta (seven examined).—Atheroma was extensively present in six of the seven arteries examined, and the changes were more advanced in this vessel than in any other in the body. Only one did not show atheroma.

The Superior Iliac Arteries (fourteen examined).—Ten of them and markedly atheromatous, especially in their upper schoolmaster (remaining four were not involved).

desirable, such *the Hypogastric Arteries* (fourteen examined).—The specimen and girl were more subject to atheroma than the to the involvement of the fourteen examined were markedly balanced girl. is on both sides we are affected to much

the same degree. In one of them the orifice was very much narrowed, and there was an aneurysm and dilatation of the vessel just beyond. I am not sure that I have seen any other changes.

The External Iliac Arteries (fourteen examined).—Only one of these showed a well marked atheroma. Five showed a few small patches, and six were quite free.

The Coeliac Artery (seven examined).—Three of these showed patches of atheroma, with consequent narrowing of the orifices of the branch vessels. Four did not show any atheroma.

The Superior Mesenteric Artery (seven examined).—In four specimens the artery was narrowed at its origin by sclerosis, but a very prominent feature in my analysis was the comparative freedom from atheroma of the greater part of the main stem of the vessel, and the branches into which it divided. Only in one ramus did I find a single patch of atheroma, and only in one subject was the main stem markedly affected.

The Inferior Mesenteric Artery (seven examined).—Except in one case the artery was absolutely free.

The Hepatic Artery (seven examined).—This vessel was extensively atheromatous in one case only, and in all the others it appeared to be healthy.

The Renal Arteries (fourteen examined).—Ten of these showed a moderate degree of degeneration. Four were not involved.

The Splenic Artery (seven examined).—Four showed fairly extensive atheroma in the main stem of the vessel. The orifices of the pancreatic branches were involved.

The Pudendal Arteries (fourteen examined).—Eleven of these showed atheroma in an extensive degree in the pelvic part of their course.

The Superior Gluteal Arteries (twelve examined).—None of these were very markedly affected. Their walls were extensively sclerosed, and the affection was usually bilateral.

The Inferior Gluteal Arteries (ten examined).—Six of these showed patches of atheroma, but they were not so much affected as the superior gluteal arteries. The remaining four were not involved.

HEAD AND NECK

The Common Carotid Arteries (sixteen examined).—Just as the aorta was markedly atheromatous at its bifurcation so the common carotid was extensively involved in the region where it divides into internal and external carotid branches. At its origin on the right side from the unominate patches were plentiful. The main trunk was found to be patchy, but in a much less degree. Location of the sixteen arteries examined showed atheromatous changes.

The External Carotid Arteries (sixteen examined).—Only three of these showed atheroma to a moderate extent, the remaining thirteen did not show any.

The Internal Carotid Arteries (sixteen examined).—This vessel in the neck and carotid canal was subject to a very small amount of atheroma. The part of it which lay in the cavernous sinus was affected extensively. In eleven of the sixteen arteries examined this part of the vessel was affected with dense plates of calcareous degeneration and was frequently sacculated.

The Subclavian Arteries (sixteen examined).—In eight of these atheroma was very marked. Usually the first part was more involved than the second or third part. Four vessels did not show any.

The Superficial Temporal Arteries (fourteen examined).—Contrary to my expectation this vessel was affected on the scalp in only two of fourteen examined.

The Internal Maxillary Arteries (eight examined).—Only two of these showed small deposits of atheroma.

The External Maxillary Arteries (ten examined).—Two of these on the face showed atheroma, and all the others were free.

The Vertebral Arteries (eight examined).—Two of these showed a large patch near their termination. Four were not affected.

The Basilar Artery (four examined).—In two of these atheroma was very well marked, two were not affected.

The Anterior Cerebral Arteries (eight examined).—Two of these showed atheroma, and six did not.

The Middle Cerebral Arteries (eight examined).—Four of these showed atheroma, and four did not.

The Posterior Cerebral Arteries (six examined).—Two of these showed atheroma, and four did not.

THE EXTREMITIES

Lower Limb

The Femoral Arteries (eight examined).—All showed well marked atheroma both in the femoral triangle and in Hunter's canal.

The Profunda Femoris Arteries (eight examined).—In one the artery was extensively involved, in five moderately, and in two it was healthy.

The Popliteal Arteries (eight examined).—All showed well marked atheroma, which extended to the termination of each vessel and involved the origin of the tibial vessels. In two

cases the popliteal artery was more severely affected than the femoral.

The Posterior Tibial Arteries (six examined).—Five of these were affected, three of them very extensively throughout their whole course, causing great narrowing and almost complete occlusion in some parts of the vessel. Only one was healthy.

The Peroneal Arteries (five examined).—Four of these were affected, two extensively, and the other two to a less extent. They were involved in the same bodies as the posterior tibial.

The Anterior Tibial Arteries (four examined).—Two were affected and two were free. These vessels are not so much involved as the arteries in the posterior crural region.

The Plantar Arteries (eight examined).—Beyond slight involvement of one lateral plantar at its origin from the posterior tibial artery, the vessels in the sole of the foot appeared healthy.

The Dorsales Pedis Arteries (four examined).—Two of them were extensively sclerosed, and two were not involved. The affection was most marked at the origin of the artery in front of the ankle joint.

The Medial Circumflex Arteries (seven examined).—These arteries were moderately affected in five of the seven examined.

The Lateral Circumflex Arteries (five examined).—This vessel was much less involved than the former. There was a small patch in one artery only.

Upper Limb

The Axillary Arteries (twelve examined).—Only one was extensively affected, two were moderately involved, there were small patches in three others.

The Brachial Arteries (twelve examined).—Beyond a small patch in one they all appeared quite healthy.

The Radial Arteries (eleven examined).—Only in two was the artery affected, and it was limited to a part three inches long just above the wrist joint. Eight were unaffected.

The Ulnar Arteries (twelve examined).—Only one of them had patches of atheroma, and it was limited to a part two inches long, just proximal to the wrist joint.

The Palmar Arch was not affected in any of the twelve specimens examined.

THORAX

The Pulmonary Artery (four examined).—I did not find atheroma in these vessels.

The Ascending Aorta (four examined).—Only one moderately affected, three were not involved.

The Arch of Aorta (four examined).—Three were involved to a small extent.

The Descending Aorta (four examined).—Three showed atheroma, one of these being very badly affected.

The Innominate Artery (six examined).—Four were markedly sclerosed, and two were not involved.

The Right Coronary Artery (four examined).—Three of these were affected to a moderate extent.

The Left Coronary Artery (four examined).—One was very badly affected, two were slightly involved and one was free.

The Mitral Valve (four examined).—Three were affected, one extensively on both cusps.

The Tricuspid Valve (four examined).—I did not find any signs of atheroma on this valve.

Medium sized arteries such as the lingual, external maxillary, superior thyroid, inferior epigastric, palmar, and plantar, did not present signs of degeneration which could be seen with the naked eye.

SUMMARY

In any one body the distribution of arterio-sclerosis was variable. Its presence in one artery was no indication that arteries in other regions would be involved.

The abdominal aorta, common iliac, femoral, and popliteal arteries were more frequently and more extensively affected than any other vessels in the body.

The internal iliac arteries were more commonly involved than the external iliac arteries.

It was a striking fact that the mesenteric arteries were seldom the seat of degeneration. In one instance only was the inferior mesenteric artery affected.

The prietral vessels in the pelvis, especially the gluteal and pudendal arteries, were affected to a very marked degree. They offered a comparison with the visceral branches in the pelvis, which were seldom involved.

The portion of the internal carotid artery which lay in the cavernous sinuses, and the part involving its bifurcation into anterior and middle cerebral arteries, frequently presented arterial degeneration of a very advanced degree. The vessel wall in this region was usually sacculated. Compare that with the cervical portion of the internal

carotid, which was subject to a very small amount of degeneration.

The vessels of the lower limb were more frequently and more extensively affected with arterio-sclerosis than those of the upper limb. In one specimen only was the axillary artery markedly involved, and only in one brachial artery was a small patch of degeneration present. A very different condition was found in arteries of approximately the same calibre in the lower limb, where the femoral and popliteal arteries were extensively affected.

The radial arteries (when involved) showed degenerative changes just above the wrist-joint, but were not affected higher up.

The tricuspid valve and pulmonary artery were not implicated in any of the specimens which I examined. They offer a striking comparison with the mitral valve and thoracic aorta, both of which were found to be a frequent site of degeneration.

DISEASES OF THE PANCREAS

GROSS and GULEK, in a treatise on the diseases of the pancreas,¹ have endeavoured to present a complete account, both from the medical and the surgical point of view, of our knowledge of the subject at the present time. Although based on the authors' own experience, the book gives consideration to the views of others, and, apart from being a storehouse of facts, indicates the present movement of thought in this branch of pathology. Comparing our knowledge to-day with that of twenty years ago, the authors have to confess that progress has been slow as compared with the advances made in some other branches of medical science, and the nature and treatment of many diseases of the pancreas still remain as obscure as they were at that time. In dealing with the subject of acute haemorrhagic pancreatitis, or acute necrosis of the pancreas, as the authors consider it would be more accurately termed, the various theories of the cause of death in that disease are discussed, and the view is adopted that it is due to poisoning by absorption of the pancreatic secretion. It has been shown that the implantation of sufficiently large portions of pancreas into the peritoneal cavity leads to death accompanied with all the symptoms of acute haemorrhagic pancreatitis, and a similar result is obtained if, by section and reimplantation of one of the ducts, part of the pancreatic secretion is diverted into the peritoneal cavity. Some further observations of Gross and Bergmann, to whom this view is due, tend to confirm it, for they discovered that an active immunity could be established by preliminary injection of increasing doses of typsin, the fatal issue and the necrosis of the organ being thereby prevented. With regard to the treatment of acute haemorrhagic pancreatitis, although slight cases may recover while severe cases without operation are almost always fatal, it is unfortunately impossible to distinguish between them with any degree of certainty, or to be sure that a mild case will not have fatal sequelae. The authors therefore make it a rule to operate in all cases, and to operate as early as possible, irrespective of the existence of shock, which, in cases of any severity, persists till death. The aim of the operation being to relieve the tension in the pancreas and to drain off the exudates, a median incision in the epigastrium is recommended as leading most directly to the organ and permitting a survey of it and its surroundings in their entirety. Stress is laid on the importance of relieving the tension in all parts of the organ, and not merely in the obviously diseased portions, and of draining through the small omentum as well as through the omental sac and transverse mesocolon. During the last ten years the mortality after operation has declined from 60 to 56 6

¹ *Die Erkrankungen des Pankreas* Von Dr. O. Gross und Dr. N. Gulek. Enzyklopaedie der klinischen Medizin. Berlin J. Springer 1923 (Sup. pp. 8vo pp. viii + 385 66 figures. Paper cover 6 45 dollars bound 7 90 dollars.)

per cent, and further reduction can only be looked for in the direction of an earlier diagnosis of the disease.

With regard to carcinoma of the pancreas, Culcke has collected records of twenty-four cases of partial or "total" resection. The mortality after these operations amounted to 50 per cent, and of the patients who survived none lived longer than six months. The only defect to be detected in the book is the somewhat brief reference to the insulin treatment of pancreatic diabetes, excuses for this are offered in the text.

PREPARATION OF THE PATIENT FOR OPERATION

"To lessen the risk of operation" is a literal translation of the title of a small work written by DETAIL in LANSBURG under the conviction that the failure of operations is more often attributable to a lack of attention in the examination and preparation of the patient than is generally supposed. If the primary responsibility for the success of an operation rests on the surgeon, the duty of the physician is by no means merely subsidiary. The author points out that the operative risk depends more or less upon him, he is responsible for having examined and ascertained the condition of the patient, and it is by his collaboration with the surgeon that the resistance of the patient, upon which in the majority of cases the success of the operation depends, is sufficiently sustained. The author has accordingly collected together, in a small compass and in a convenient form, directions on all those matters which are accessory to the operation itself, and which, if neglected, lead to failure.

The first part of the work deals with the methods of estimating the patient's power of resistance. Details are given of the means of gauging the functional efficiency of the liver, kidneys, circulatory system and blood, and of the measures to be applied to correct functional derangements. The second part deals with the choice of the anaesthetic and the technical details of its administration, the third with the preliminary treatment of infected patients. In this the objective is stated to be the promotion of the defensive reactions of the organism and the measures recommended are the stimulation of phagocytosis by the injection of colloids, the sensibilization of the phagocytes by injections of vaccines, the neutralization of toxins by means of specific serums, and the promotion of their elimination by means of the administration of uroformine (hexamine). As an adjunct to local disinfection after the operation, discontinuous irrigation by Cajal's method as applied to various regions and organs of the body is described. After a chapter dealing with the sterilization of dressings and instruments, the prophylaxis and treatment of operative shock and haemorrhage are considered in part four, which is almost entirely devoted to the technical details of blood transfusion. The book is illustrated with numerous figures.

THE CHILD AND HIS PROBLEMS

In a little book, *The Child and his Problems*,³ Dr ALICE HURCHISON discusses a few of the difficulties which parents must face. Dr Crichton Miller in a foreword praises the avoidance of theories and technicalities in the text, thereby commending it to people who have no training in psychology. The opening chapter deals with sunshine, air, water, bodily functions, diet, digestion, and sleep, as they affect the growing child, and the importance of habit formation with regard to them is insisted upon. The author holds that, especially in dealing with children, example is better than precept, she expresses the belief that in the majority of us the child remains very slightly modified, and that it is only the minority who grow up. It follows, if we accept this statement, that if we wish to know and understand the child it is helpful to study ourselves, and, conversely, a study of the child will teach us much about ourselves.

A. Maloine et Fils 1924 (Cr. 8vo pp. 338 51 figures Fr. 15)
The Child and his Problems By Alice M. Hutchison M.D. Edin
W. F. C. Laidlaw With a Foreword by Dr Crichton Miller London
Williams and Norgate Ltd 1925 (Cr. 8vo pp. viii + 168 2s net)

The abnormal child is dealt with under the headings of "difficult," "only," and "nervous." The doctor's advice may be sought in dealing with children who fall into these categories, yet it is the parent who have to deal with them daily, and on whom they must depend for help in overcoming their difficulties. Meaning in discipline and the value of punishment are dealt with at some length. I may be asked whether, in the dictum of some paedagogues and child psychologists, "a child must never be punished in anger," there may not lurk a danger. Most children are exasperating at times, and is there not such a thing as a "righteous anger"? Parents get angry at times, being human is no credit to be given to the child for his love and understanding of his parents. One of the most beautiful things to be observed in children is the way they forgive their parents. The author does not discuss this side of the question. One chapter is on the banishment of fear, which may become a great handicap in life, and another on the formation of habits, a few words are said on the vexed question of religious education of the young.

The study of childhood has advanced by leaps and bounds since the early Victorian days, when almost every childish impulse was repressed, and such impulses as unconsciously their elders very severely so. Now, it is recognized that harm may be done to the child by repressing impulses in the wrong way and at the wrong time. So much is talked and written of the possibility of causing hidden complexes that parents anxious to do their utmost for their children may well feel that omniscience is demanded of them. Those who feel this anxiety would do well to read Dr Hutchison's book, for therein they will find help and guidance.

NOTES ON BOOKS

KLEMMER's work on bacteriological and serological technique⁴ is designed as a *tabulae inveniendi* to be placed on the laboratory table as a book of reference. It professes to furnish information on every technical detail, from the most simple to the most complicated. It will be of use, therefore, to the general practitioner who has little experience, as well as to the research worker who requires information on recent developments and improvements. In a book intended for reference the arrangement of the subject matter is of prime importance, and the author has taken pains to present the subject in a form which renders any required detail rapidly accessible. In this connection a good index is indispensable, but in addition to this a very well prepared table of contents has been provided, which gives the geography, as it were, of the book at a glance, not merely as regards chapters and sections, but also as to paragraphs. This table facilitates reference to a notable degree. With regard to modern improvements, the author has selected from the enormous literature of the subject such methods as appear to him to be of fundamental importance, and has in most cases given a reference to the original papers. The descriptions are terse and theoretical discussions are omitted. The book is adequately furnished with good illustrations.

MEDICAL AND SURGICAL APPLIANCES

X Ray Generators and Accessories
MESSRS. WATSON AND SOXS (Electro Medical), Limited (43, Parker Street, Kingsway, London), have sent us a copy of their general catalogue covering the whole field of x ray generators and accessories. We note in one section the formidable list of items in a complete installation for a radiological department, with apparatus and materials for diagnosis, dental radiography, and superficial and deep therapy. The total cost is £2,255, the shipping and delivery in London is £266 10s. Among the newer pieces of apparatus listed is a hospital transformer outfit for generating x rays, a portable x ray outfit, which although it reaches as high a figure as 90,000 peak volts can be connected up with the ordinary domestic lighting circuit and a constant tension apparatus for include a new form of barium meal said to be indistinguishable from blance mange and a new pattern of Potter Bucky diaphragm in which the travel of the grid during exposure is so arranged that but interesting section dealing with radium.

CONVENTION OF ENGLISH-SPEAKING OPHTHALMOLOGICAL SOCIETIES

OPENING CEREMONIES

THE Convention of English-speaking Ophthalmological Societies, under the presidency of Mr THURGOOD COLLINS, to the assembly of which in London last week reference has already been made, was formally opened in the Memorial Hall, University College, on July 14th, by the Right Hon NEVILLE CHAMBERLAIN, Minister of Health, who offered to all the delegates from overseas a cordial welcome, and congratulated the profession in this country upon the energy with which it was organizing upon a national scale for the preservation of the most precious of all the special senses.

The AMERICAN AMBASSADOR, on behalf of the visitors, thanked the English organizers for their cordial welcome and their warm hospitality. Delegates from the various ophthalmological societies taking part in the congress were then presented to the Minister.

After the presentation of the Nettleship Prize to Professor Whitnall of Montreal for his classic work on the anatomy of the orbit, and the investiture of the President by Mr W T Holmes Spicer with the new Crichton Memorial Badge, Mr TREACHER COLLINS delivered his presidential address on the elimination of eye disease. He drew a hopeful picture of progress in the past, but much remained to be done. He made many interesting and arresting suggestions for the future, and pointed out that prophylactic endeavour should not only be national but international, for disease was the common foe of all nations, and active co-operation on the part of all of them was required to build up a healthier, more moral, and more intellectual man.

THE BOWMAN LECTURE *Foundations of Vision*

The Bowman Lecture, which was delivered by Sir JOHN PANSONS, C B E, F R S, formed the outstanding contribution to the proceedings of the convention. Choosing as his subject the foundations of vision, the lecturer evolved and elaborated the thesis that the physiological processes concerned in vision, the anatomical basis of these processes, and their psychological counterparts, could be divided into two great groups—protopathic and eperitic, and, further, that the conception was not limited to vision and to ophthalmology, but embraced the whole domain of the physiology of the senses, and the psychology which is the conscious expression of that physiology.

The protopathic response was the more primitive and undifferentiated, of essentially utilitarian, vital import (that is, concerned with processes on which survival and existence depended), and possessed that potential plasticity which permitted of differentiation along many lines. The eperitic was differentiated and evolved from the cruder protopathic. It was of gnostic import, and while retaining many of the characteristics of the protopathic response, provided an active dynamic plasticity in a narrower field, inasmuch as it was endowed with a richer and more sharply defined cognition. This conception of a dual mechanism was supported by anatomical observations and physiological experiment on man and the lower animals, and by clinical observations. Very low down in the animal scale the most primitive visual organ, a single receptor cell, responded to incident radiation by one primitive indubitable response—a motor, directional one. This, the fundamental protopathic response to light, was traced in its evolution to the elaborately co-ordinated photostatic mechanism for equilibration and co-ordination met with in man, a system whose reflexes were centred in the mid-brain and differentiated and integrated in the cerebellum. The eperitic system at

this level was represented by the fibres concerned in stereognostic perception. The same duality obtained in the sensory functions of vision. The protopathic light sense was represented by scotopic vision (the vision of dark adaptation), and, as such, was vague, crude, and undifferentiated, lacking localization and discrimination. Photopic vision had the characteristics of eperitic sensibility, with its meticulous exactitude of localization and discrimination, and its qualitative differentiation in the perception of colour.

In the retina the protopathic mechanism was represented by the rods, the eperitic by the cones. The appreciation of movement, a function largely of the former, was a primitive biological feature on which depended the preservation of life (that is, of vital import), it was therefore protopathic in nature. Colour vision, a function of the latter, was the highest differentiation reached by eperitic sensibility. Phenomena of fatigue, discrimination of depth, etc., could well be explained physiologically on the basis of induction. In the central nervous system the optic fibres to the superior colliculus and their connexions were the most primitive phylogenetically, their function was photostatic, then nature was therefore protopathic. The fibres to the geniculate body were largely eperitic, those to the thalamus, concerned with vision and stereognosis, belonged also to the eperitic system.

The lecturer concluded by expressing the opinion that ophthalmology had too long been content to apply past knowledge, and that future advances would not depend, as heretofore, on refinements of operative technique, but would rather depend on and be revolutionized by an increased knowledge of the biochemistry of the eye and the physiology of vision.

SYMPOSIUM ON THE EVOLUTION OF BINOCULAR VISION

Professor ELLIOT SMITH opened a discussion on the evolution of binocular vision from the point of view of comparative anatomy. The change from monocular to binocular, and from binocular to true stereoscopic vision, with the consequent acquisition of a wider field and an appreciation of detail, was the predominant factor in the evolutionary development of man, and formed the substratum whereon his intellectual supremacy was built. The increased reliance on vision instead of smell as the predominant sense, first evolved in the early Eocene period, when the basal stock of the true primates first made their appearance. Man's ocular outfit was thus older than man himself, and depended, at the first, on the conditions of arboreal life. The progeny of this stock had evolved to different degrees, leaving a series of intermediate forms, which represented stages in the evolutionary progress, and served as clues to the study of their complete development in man. A particularly useful clue was found in *Tarsius*, a very early primate which had completely escaped further specialization. By the use of such intermediate surviving forms an evolutionary history of the full stereoscopic vision of man could be built up. The speaker outlined the evolution of the eye and orbit, laying stress on the recession of the snout, a process which rendered a binocular field possible, the growth of the dominating occipital cortex, and the late appearance of the mires, whose acquisition allowed the appreciation of detail, and the evolution of the motor centres in the mid-brain and prefrontal cortex, which controlled involuntary automatic movement of the eyes. This, replacing the voluntary monocular method of lower animals, permitted concentration of attention on the object seen instead of on the muscular effort of focusing. It was a prepotent factor in the development of skilled movements and the power of experimentation, and consequently of intellectual advance.

Sir FREDERICK MOTT dealt with the cerebral part of the subject. Referring to his work with Sharpey-Schafer on the simultaneous stimulation of the frontal and occipital centres, he showed how the former overcame the latter. Experimental work on monkeys and observations on man demonstrated the development of the agranular motor area in the frontal lobe, which served as the coordinating centre for the muscular and reflex systems of head, neck,

and eyes. This was reinforced by fronto-pontine cerebellar impulses, and was linked up with cerebral processes of association in the highest level, where syntheses of retinal and kinaesthetic images occur.

Professor WHITWALL traced the evolution of the muscular apparatus subserving the need of binocular vision. The lower animals moved their heads, not their eyes. The more an animal felt the need to increase its visual fields, the more developed its eye muscles became. He followed their evolution in the gradual movement of the eyes from the side position on the head to the front. The process could be divided into two stages: the attainment of parallelism in the visual axes in place of divergence, and the further development from this into convergence. In each stage the changes in the muscular mechanism followed very definite laws.

Sir ARTHUR KEITH summed up the conclusions of the previous speakers, and outlined the main modifications undergone by the orbit and skull in the evolution of binocular vision. He suggested as a more scientific term bivoceate or bimacular vision, since "binocular" vision was widely distributed in the mammalian orders. The primates possessing this form of vision might well be called Bivoceates. In the speaker's opinion the development of bivoceate vision had nothing to do with the reduction in the size of snout or any skull changes, nor was it a necessary result of arboreal life. Rather was it closely linked with the means of locomotion, which was the dominant factor in the evolution of true primates. All bivoceate primates were jumpers or springers. As such they must be able to judge the distance from branch to branch, to estimate the safety of the support offered, and to see and appreciate beyond the first steps a succeeding series of footholds, having no leisure to take cognizance of the individual movements of foot, hand, or eye. In the language of the jungle the old golfing axiom read "Keep your eye on the branch." Supported by comparative evidence, he expressed the opinion that the true source of the superiority of man's vision lay, not in the kind of eye or skull with which he had been provided, but in the brain which had grown up behind his eyes. The evolutionary machinery which had thus transformed the visual world was exceedingly complicated. It involved not only all the parts which went to make up a perfect eye, but all the parts concerned, peripherally and centrally, in eye movements, and the connection of these centres with other sensory, motor, and psychical centres. When they had explained how man came by his vision, they would have explained the most difficult part of the whole problem of evolution, the most likely clue to which would appear to be in the study of development, especially through the light obtained by experimental embryology.

THE OFFICIAL BANQUET

The official banquet which terminated the proceedings of the convention took place in the Guildhall on the evening of July 17th, Mr TREACHER COLLINS being in the chair. H. R. H. the DUKE OF CONNAUGHT, in replying to the Royal toasts, expressed his gratification and pleasure at meeting so many distinguished ophthalmologists. remarking on the constitution of the convention, he said that the more the English speaking peoples co-operated, and the closer their union, the greater the prospect of peace and prosperity for the whole world. The PRESIDENT, in proposing the toast of the English-speaking ophthalmological societies, emphasized the common origin and the common inspiration of the peoples represented, and the common purpose of their gathering—the love of ophthalmology. Sir JOHN H. PARSONS, in replying for the Ophthalmological Society of the United Kingdom, spoke of the debt which America owed to English ophthalmology. Their American brethren were now repaying that debt, unlike the Greeks, they did not repay in gold, but rather in the coinage of inspiration returned. Dr DE SCHWENITZ, on behalf of America, and Dr GORDON BYERS on behalf of the Colonies, paid a warm tribute to English hospitality, and expressed appreciation of English inspiration.

Mr J. H. FISHER proposed the toast of the guests, which was responded to by Sir GEORGE WYATT TRUSCOTT, Sir HUMPHRY ROLLESTON, and Sir JOHN BLAND-SUTTON.

THE BRITISH SOCIAL HYGIENE COUNCIL

The body which has been known for the past eleven years as the National Council for Combating Venereal Diseases has changed its name to the British Social Hygiene Council, and under that description held its first annual meeting on July 9th, when the Right Hon. Sir ARTHUR GIBBS presided. In a statement circulated at the meeting it was emphasized that the alteration of name means an extension of the attack on venereal diseases, which now is to be waged on social as well as on medical grounds. Increased prominence is to be given to "the elimination of those conditions of life which tend to foster promiscuous intercourse and the spread of disease"—a quote one of the recommendations in the report of the Committee of Inquiry on Venereal Diseases—and efforts are to be made to foster character training in the young and to uphold the integrity of family life.

Sir ALCKLAND GIBBS pointed to the definite diminution in the number of new cases of infection recorded at the clinics as an evidence of the great work which the Council had accomplished. On the medical side the attack on venereal diseases had made distinct progress, but the medical side, although of vast importance, did not fill the whole of the picture. Individual and social measures must be kept in view, leading especially to the preservation and strengthening of the family as the basic social unit and the promotion of a high and equal standard of conduct for men and women.

Viscount WILLINGDON spoke briefly on his experience of the campaign against venereal diseases in India, and Mr. GARLICK SPENCER, a member of the board of directors of the American Social Hygiene Association, brought the greetings of that body, and gave an outline of the history of the American movement.

In the evening a dinner was held at the Hotel Cecil, when the toast to the Social Hygiene Council was proposed by Lord MURRAY, President of the Divorce Court. He said that while ordinarily he was suspicious of changes of name, which generally meant that there was something to conceal, he felt that in this instance the change did really correspond to a widening of ideas and policy. He was conscious of the magnitude of the task to which the Council had set itself. Until recent years the subject of the social evil had been avoided, and it was a striking change to see people both of his own and of the younger generation now earnestly and candidly grappling with the problem. The old taboo was partly due to the natural illiness of the human mind, and partly to a perverted sense of right and wrong, but it had been discovered that it was not possible to inculcate virtue by taboo.

Sir ALCKLAND GIBBS, in responding, remarked how vividly aware he had been made, during the time that he took a part in the government of the country, of the way in which venereal diseases were eating into the health and vitality of the nation. It was in those days of the war, when the national stocktaking was close and accurate, that it was realized how far the social evils cut into the national efficiency. Mr. GNEVES-LORD, K.C., M.P., proposed the health of "The Guests," to which Surgeon Vice-Admiral CHAMBERS, Director-General of the Navy Medical Service, responded, and Miss SEVERIDGE, C.B.E., proposed the health of the sister organizations, the Social Hygiene Associations in the United States, Canada, South Africa, and Australia, and the one which was shortly coming into existence in New Zealand. All these bodies worked in hearty co-operation with the British organization, and shared one another's literature and films. Brief replies were made by the representatives of some of these overseas societies. Mr. E. B. TUNNEN proposed the health of Sir Auckland Geddes.

Among those present at the dinner, in addition to the speakers, were Sir Arthur and Lady Newsholme, Lady Emmott, Lady Sydenham, Bishop Weldon, Sir Graham Stewart, and Dame Louise Aldrich-Blake.

It appears that the Society for the Prevention of Venereal Disease also has Sir Auckland Geddes for its president. This identity of presidents signifies that the old controversies have lapsed, although fusion of the two bodies has not been attained.

SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE

THE sixth annual general meeting of the Society for the Prevention of Venereal Disease was held at 12, Stratford Place on July 8th, with the president of the society, the Right Hon SIR AUCKLAND GEDDES, G C M G, M D, in the chair.

The President, in the course of his address, said there had been a very great reduction in venereal disease amounting to nearly 50 per cent, within the last five years. He did not think any one organization could claim that this reduction was the result of its labours alone, but that all who had taken part in attempting to educate the people as to the importance and dangers of venereal disease and in teaching the public how to prevent the disease might say they had contributed to this great improvement. He believed that fusion between the British Social Hygiene Council and the Society for the Prevention of Venereal Disease was undesirable, because, although both the societies had accepted the Trevethin Report, they had accepted it with quite different emphasis laid upon the different recommendations. He thought that when dealing with such a subject as venereal disease it was inevitable that those at the one extreme of thought would find it practically impossible to understand the point of view of those at the other extreme of thought, although both extremes and those between them were working for the same end. He considered that the Society for the Prevention of Venereal Disease had got hold of a very important part of the work which had to be done. What they desired to see was that the causal organisms of the different diseases should be destroyed whenever and wherever they might be found, and that this matter should be dealt with without an infusion of sentiment, which was out of place in respect to the attack upon the organisms. He thought there was a wide field for co-operation with those who laid the emphasis on the moral and emotional side, and he considered that an attempt to get all who were working for the prevention of venereal disease into one society would result in a great loss. In the belief that the continuance of the two organizations was good, and that it was really better than fusion, he had, after careful consideration, accepted the position of President not only of this society, but of the other society, believing that in that way, although the societies continued as separate and independent bodies, it would be possible to present a united front to the Government of the day or the department of State concerned with the health of the people. It must be obvious to anyone who understood the parliamentary situation that all Ministers, including the Minister of Health, were extremely busy, and it would be wise for the society to make up its mind to concentrate upon getting a definite reply from the Ministry of Health in the autumn months of this year and not before.

The President then proposed that the following resolution should be laid before the Government in the autumn:

That this meeting with great respect urges the Government to give effect without further delay to the recommendations contained in the Trevethin Report which the Minister of Health has stated have been accepted in principle and further begs to call the attention of the Minister of Health to the resolution submitted to the Ministry of Health at the annual general meeting of the society in July 1924 requesting the allocation to the Society for the Prevention of Venereal Disease of an equitable proportion of any sum set aside for the education of the public regarding venereal disease and its prevention to which no reply has yet been received.

Mr WANSEY BAYLY, the honorary secretary, reported the work of the society during the past year. A new situation, he said, had arisen owing to Sir Auckland Geddes having accepted the presidency of the British Social Hygiene Council, and, therefore, the Society for the Prevention of Venereal Disease must do its best to help Sir Auckland to make the most of this new situation. Although the society consisted chiefly of scientists, practical idealists and reformers, they must endeavor to look at the matter from the political point of view, even if this aspect of the case would not appeal to them all. Important progress had been gained during the last year by the acceptance of the principle of immediate self disinfection

by the British Social Hygiene Council, by the appointment of Sir Auckland Geddes to the leadership of the British Social Hygiene Council, and by the acknowledgement of the Ministry of Health that the evidence of witnesses before the Trevethin Committee was available for reference or publication.

Mr HARRY MACHIN, in the absence of Sir Arbuthnot Lane, joint treasurer, presented the financial report and annual audit.

Lady ASKWITH, in seconding the resolution, said she thought many of the members of the society would agree that Sir Auckland Geddes was right in maintaining that fusion between the two societies was not possible or desirable, and she was also sure that there would be nobody who did not feel that they were perfectly safe in the hands of Sir Auckland Geddes as President of both organizations. It was impossible to do much propaganda work without money, and that as they were the only society teaching that particular point of view it was important that they should be supported by Government money.

Mr BASIL PETO, M P, in supporting the resolution, expressed his pleasure in hearing that the President had also taken the position of President of the other society. He entirely agreed with the conclusion reached that fusion would not have been a source of strength, but would have been a weakness to the cause about which they were all so keen, and he thought the best possible liaison between the two societies was to have one head of the two societies, because then the members of either society need not change the views they hold. He considered the present position unsatisfactory, as it was now over two years since the committee presided over by Lord Trevethin reported, and no steps had been taken to carry out what the society regarded as the most important part of the report—that which dealt with the sale of the necessarily simple preventive disinfectants at chemists' shops. While the present hesitation was deplorable, he fully realized that the Ministry was absolutely snowed under with work at the present time, and that in such circumstances even a small addition to the Government programme could not be expected. He thought the question should be raised when the vote for the Ministry of Health came before the House of Commons.

Mr A J BENNETT, M P, said that the society could not expect to obtain all its revenue from a very limited number of persons, and that it was only right they should try to get funds from the public.

The resolution was put to the meeting and carried unanimously.

ROYAL MEDICAL BENEVOLENT FUND

At the last meeting of the Committee twenty-four cases were considered and £386 16s voted to twenty-three applicants. The following is a summary of the new cases relieved:

M D Edin 1890 aged 71 who at one time practised in South Africa. He is bedridden and cannot stand. He has also chronic bronchitis. Two brothers meet the nursing home fees. Voted £5.

Daughter aged 48 of L R C P Edin who died in 1924. She is mentally not able to support herself and her only income from investments amounts to £48 a year. A brother in Canada gave £20. Voted £15 in twelve monthly instalments.

Daughter aged 58 of M R C S 1843 who died in 1877. Applicant lost most of her money through untrustworthy friends. She is now left with capital which brings in 15s a week but she has had to draw upon this capital at the rate of 32s 6d a week to meet expenses. She lives with an adopted sister. Voted £18 in twelve instalments and referred to the Guild for clothing.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, K B E, C B, M S, at 11, Chandos Street, Cavendish Square, London, W 1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and gals holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W 1.

British Medical Journal.

SATURDAY, JULY 25TH, 1925

BATH

THE ninety-third Annual Meeting of the British Medical Association has opened in the pleasantest and most favourable circumstances in every respect save one—the deeply regretted illness of the new President. A few days before the opening of the Association's new house in London news came that Dr F G Thomson was in bed with a severe attack of pleurisy, and, as recorded in our last issue, he was unable to attend to be presented, as President Elect, to the King on July 13th. Although Dr Thomson's strength is maintained and his progress is satisfactory, his condition has made it impossible for him to take any part in the work or social activities of the Annual Meeting this year. The Local Executive met only last week and unanimously agreed to appoint Mr W G Mumford, F.R.C.S. (who has earned out, with Dr R G Gordon, the duties of Honorary Local General Secretary), to act as deputy for the incoming President.

In the Presidential Address printed on the first pages of this issue Dr Thomson has given a masterly summary of the history of this ancient Somerset city as a health resort. The Address was read to a large audience in the Palace Theatre by the President's son, Mr Malcolm Thomson, B.A., of Sidney Sussex College, Cambridge. In some respects Bath stands alone among the cities of Great Britain, for only in it do the works of the Romans still exist in some completeness, and may almost be said to be still in use. It owes this distinction probably to the circumstance that it possesses the only really hot springs in the British Isles. To these springs the permanent use and occupation of the site is most likely due, for without them Bath would almost certainly have shared the fate of many another Roman city over which the sheep and cattle now graze or the plough passes. Nothing is more tantalizing to the curious student of history than the completeness of the curtain which descended on British history after the Saxon conquest only to be lifted bit by bit as Anglo-Saxon civilization slowly developed.

Of Bath as a health resort we know from the buildings as yet discovered that it had a great vogue as a watering place. The Romans so highly valued the advantages of a constant flow of hot water that it may be said that wherever in the Roman Empire there were hot springs—in Europe, Asia, or Africa—there also may be found traces of Roman occupation. Although these traces were less completely obliterated on the continent of Europe than in Britain yet the story of Bath in the Middle Ages and the early Renaissance, as told so well by Dr Thomson, is not very different from the story of such hot springs as those of Aix les Bains, which was so well told by Gabriel Perouse in a book which was reviewed in this JOURNAL two years ago.¹ There was the same squalor and lack of decency and sanitation and very much the same amusements seem to have been popular in the two places, particularly gambling.

Perhaps Bath in the eighteenth century was more of a place of pleasure than Aix. Dr Thomson gives

a lively account of the visit of Charles II and what can hardly be called his harem, for its far number were by no means secluded, nor did they always reserve their favours for their swarthy master. Perhaps, as Dr Thomson hints, the object of the journey would have been nearer achievement had they stayed behind in London leaving the King to restrict his attentions to his lawful spouse. Ever since the 17th century Bath has not been wanting in skilful and learned physicians whose advice and treatment have probably had therapeutic value equal at least to that of the waters. Much also may justly be credited to the charm of the neighbouring country, helped by the beautiful and diversified architecture of John Wood, combining to produce an aesthetic effect healing and soothing to the troubled mind. The Bath physicians of to-day, however, have at their disposal a knowledge of the radio-active and other properties of the water, which their predecessors did not possess, and which enables them to prescribe in a more scientific and less empirical manner.

The literary associations of Bath are many, and are touched upon by Dr Thomson, yet there are some which no doubt want of time made him omit but which we cannot help recalling. Whether or not we accept either of the legends as to the origin and discovery of the waters, the records of which Mr Pickwick found conveniently forgotten in a lodging house bedroom, Dickens's description of the place in its state of temporary eclipse is amusing and instructive. The only comment we would make on the later legend, which attributes the waters to the miraculous and perpetual flow of the tears of Prince Bladud, is that if that were the origin a greater degree of salinity would be expected. To many of us Bath of the late eighteenth and early nineteenth centuries is indissolubly associated with Jane Austen, and we cannot read or hear the names of Malmoe and Gay Street without conjuring up visions of Anne Elliot and Captain Wentworth, or Pulteney Street without thoughts of Catherine Morland and her real and false friends. Nor can we omit from the list of names of those who have made Bath famous that of the great novelist, criminologist, and chairman of quarter sessions—Henry Fielding, who was long and in various ways associated with the city and its neighbourhood. He suffered from gout and was ordered to Bath for the treatment of jaundice, "in which case the Bath waters are generally reputed to be almost infallible." This is a tribute from a great man which should not be forgotten.

Since the days of the first establishment of Aquæ Sulis Bath has had its violent ups and downs of fortune, but we may now safely assume that its position is secure as a thermal water cure, and that future changes will only be for the better.

ANNUAL MEETING NOTES

THE ANNUAL REPRESENTATIVE MEETING

Friday, July 17th

FULL reports of the first two days' proceedings of the Representative Body will be found in this week's SUPPLEMENT. The brief informal notes that follow are meant to serve merely as fingerposts to some of the debates and decisions.

The first session was distinguished by an unusual absence of controversial matter. The loss of Dr Haslip and the absence through illness of the President-Elect, Dr F G Thomson, were the only sources of regret in proceedings marked by a sense of gratitude for past work and confi-

¹ BRITISH MEDICAL JOURNAL, June 30th 1923 p 1101

dence in the future of the Association. The election of Mr. Childe, President of the Association in 1923-24, and of two members of the Canadian Medical Association to be Vice-Presidents, with that of Mr. Hallett as an honorary member of the Association, followed by Mr. McAdam. Mr. Liddle's motion to tender the thanks of the Representative Body to those chiefly concerned in the transfer to the New House, gave a welcome opportunity for free and generous expression of these sentiments. In proceedings of such a nature the Mayor's welcome to the Association was an agreeable incident, and his obviously sincere offer of unlimited hospitality was warmly received. In the final stage of the proceedings for the affiliation of the Canadian Medical Association, in the report on the New House, and even in the finance report, the meeting found occasion for the expression of congratulation rather than criticism, and such discussion as took place showed only that the representatives' confidence in the Council as the executive of the Association was based upon consideration of the Annual Report, and not on failure to appreciate the responsibilities involved in its acceptance. The response to Dr. Bolam's hint about future developments was unmistakable. A like spirit was shown in the reception of the Journal and Science Committees' reports. The project for the *Journal of Pediatrics* was warmly welcomed, and readiness for an extension of the work of the Science Committee (and incidentally of its expenditure) was sufficiently indicated. An estimate of the relative space allotted in the *Journal* to science and to other matters, including medical politics, reminded the meeting that things are not always what they seem. In this connexion the motion for publication of fuller reports of committee work was useful, if only as directing attention to the means of publicity already available. The agenda for the afternoon covered medical ethics and national health insurance. Under these heads the relative absence of controversy was even more noticeable. The Ethical Committee is to be congratulated on the acceptance of the revised report on indirect advertising, though the final test will obviously be the measure of its practical application by the profession. The first active debate was based on the Dartford motion to amend Ethical Rules 5 and 6. As so often happens, the motion was based on a misapprehension of the possibilities of action under the existing rules, but the discussion was useful as clearing up points actually in doubt in many Divisions. The motion for consideration of certain aspects of the practice of psychoanalysis raised a point of difficulty which the Representative Body clearly felt was beyond its competence. The general feeling seemed to be that there are cases in which it is best to let ill alone, for fear that worse may follow, but Dr. Bolam's suggestion to transfer the onus of consideration to the Council was welcomed by all, including Dr. Parry, with whose motives in speaking to the motion formally proposed by Dr. Lyndon there was general sympathy. The Insurance Acts discussion was not without interest, for it showed clearly enough the growth of confidence in the Council's method of taking the measure of professional opinion without exceeding its mandate from the Association. When the strongest protest on an alleged unconstitutional action is found to be that of one who, in Mr. Turner's words of himself, "doesn't want to move any motion or anything," but feels it his duty to lodge a protest, no particular effort to justify the action of the Council seemed necessary. The Clchester and Worthing and Bolton motions afforded a useful opportunity for reassuring the profession as to the activity of the Insurance Acts Committee in a matter of real significance, and the spirit in which they were discussed was encouraging. The Durlington motion on the action of co-operative societies in connexion with prescriptions under the Insurance Acts also showed healthy local activity.

Saturday, July 18th

The atmosphere of the meeting on Saturday was far more "normal" than on Friday. Points of order or disorder were raised more freely, and feeling was sufficiently strong to demand one vote by roll call. Three points of major importance were under dispute: the extension of the activities of the Association to the provision of locum-tenent bureaux, the vexed question of individual medical defence, and the definition of the constitutional relationship between the policy of the Association as laid down by the Representative Body and that of the Divisions as formulated locally. As regards the first of these, cordial support was extended to the Council's proposals. The discussion turned mainly on the method of securing for the Association effective control of the policy and practice of the proposed new company, the upshot was the endorsement of the point of principle and expression of confidence in the Council's conduct of the necessary organization. Dr. Davies, of South-West Wales, made an interesting maiden speech, raising a question as to the future effect of a policy which may establish a monopoly of agency work under the regis of the Association, on the formulation of minimum rates for assistants and locum-tenents. The discussion showed a growing appreciation by representatives of the responsibilities of the Association towards its newly qualified members. The outstanding feature of the day was undoubtedly Dr. Morton Mackenzie's opening of the discussion on individual medical defence. It was a model of clear and impartial exposition, setting out the facts of the case, distinguishing the points at issue, and summarizing the advantages and disadvantages of the several possible methods of dealing with them. Throughout the debate which followed it was unusually difficult to estimate the feeling of the meeting and forecast its decision. The speaking was well balanced, the applause impartial. Almost every member who spoke addressed himself clearly to the particular point he had selected, and while Dr. D'Ewart gave his accustomed and appreciated display of vigour, the only personal feeling shown was occasioned by Dr. James Neal's contribution to the debate. Dr. Neal, in his twofold capacity as representative of the Hendon Division and secretary of one of the medical defence societies, had a difficult part to play, he clearly played it with sincerity, and in the main with effect, though certain of his remarks might have come with greater force from any other speaker. It was unfortunate that the motion on which the debate was based in the first instance should have been one raising the issue of unconstitutional action on the part of the Council. That charge was fully rebutted before it was made, and the Representative Body clearly felt that Dr. Lyndon had no case, though he made the best of a poor opportunity. The disadvantage involved in this procedure was fortunately minimized by the attitude of the representatives, who declined to discuss anything but the real issue. On the other hand, it was noteworthy that they also declined, in the main, to discuss the point raised by the form of the organization report—namely, further inquiry. They applied themselves (with certain exceptions) to the one point, Shall the Association undertake this work? This attitude presumably accounts for the voting, which showed a measure of support for Dr. D'Ewart's following almost identical with that on the occasion of the last discussion, at Bradford. The third question—that of the relationship of the Divisions to the policy of the Association—is one good to debate but dangerous to settle. It was plain that the practical difficulties of the situation were appreciated by the representatives. Sir Jenner Verrall expressed the general feeling when he pointed out the danger of seeking the logical conclusion in a matter where the responsibility and vitality of central deliberations on the one hand, and the reality of local autonomy on the

BATH FROM BEECHEN CLIFF (From a wood engraving by Horace Gerrard)

other, are at risk. It may perhaps be said that Dr Fothergill's motion is one which might usefully reappear on the agenda of the Representative Body at decent intervals, as providing an opportunity for exposition of the constitution of the Association, its law and custom, such as was elicited from Dr Blackenbury, Mr Hempson, and Dr Bolam. The representatives showed an adequate appreciation of the position as thus explained. Apart from these three points the organization report served a most useful purpose in emphasizing the desire of the Representative Body for a forward move in the matter of post-graduate education. The strength of the sentiment on this matter, which is of great importance, may be estimated by the fact that, even under so vigilant a chairman as Dr Blackenbury, Dr John Stevens succeeded in mentioning the subject under the heading of chairman's hedges! The session closed with suggestions for using the unexpended balance of the subscription for the badge of office with which the Chairman of the Representative Body was invested earlier in the afternoon, by Dr W Douglas, supported by Dr Milner Moore, both veterans in the service of the Association.

"THE BOOK OF BATH"

The Book of Bath, of which a copy has been given to every member attending the Annual Meeting this year, is in every way a beautiful volume, and the sort of thing that Bath alone could produce for the entertainment and instruction of specially honoured guests on a very special occasion. The articles, twenty-four in number, have been written by recognized authorities in their several subjects under the editorial direction of a committee consisting of Dr A E Norburn (Chairman), Dr Vincent Coates, Mr A Leonard Fuller, FRCSI, and Mr John Hatton (Director of the Baths). Mr Hatton's share in this charming gift book is far from being his only service to members of the British Medical Association, for he con-

tributed the series of descriptive and historical notes on Bath and its neighbourhood which have appeared lately in our columns, and in all the arrangements for the success of the meeting he has taken an active part. The get up of the volume is entirely worthy of the contents. Binding, paper, typography, and illustrations testify alike to the fine taste of the editorial committee and the care bestowed upon this work by the Ballantyne Press. It is impossible in a brief notice to do justice either to the letterpress or the pictures with which *The Book of Bath* is so lavishly adorned. Its aim, as stated in the preface, is to give visitors a glimpse of the various conditions and of the succession of events which have affected both the City of Bath and the realm of England during past centuries. "The history of this city represents in miniature the history of England from the earliest known times to the present day, while around it are found the remains of the dwellings and implements of the prehistoric inhabitants of this island." Some idea of the scope of the work and the manner in which the material has been handled may be given by a bare enumeration of the chapters and their authors. The geology of the Bath district is discussed by F S Walms, Ph.D., the erosion of the Avon valley by P E Martineau, and vestiges of prehistoric man around Bath by Arthur Bulleid, F.S.A. Bath in the Roman period is sketched very ingeniously by C H B Quennell, FRIBA, and Alfred J Taylor, FRIBA, under the title of "A visit to the thermae." The story of Bath in Saxon and in Norman times is told by Reginald W M Wright, director of the Art Gallery and Libraries, and that of mediæval and Elizabethan Bath by the Rev J Byrnhmore. A chapter by Christopher Hussey gives us glimpses of men and manners at Bath in the eighteenth century, and the many-sided activities of present-day Bath are described by A E Norburn, M.D. An account of the geology of the mineral springs by R H Rastall, Sc.D., is followed by historical notes by John Hatton on the Baths

and other medical institutions of Bath, with the exception of the Royal Mineral Water Hospital, whose 190 years of service to the country are recorded in brief by T Kirby "Bath in literature," by George Stuntshury, is a paper from the pen of the eminent writer who maintains the scholarly traditions of the city. A survey of the delightful eighteenth century architecture of Bath is given by Mowbray A Green, F R I B A, and W H Devenish contributes a sketch of ecclesiastical Bath to the Reformation, with a postscript on later ecclesiastical history by "A E N." After the Rev P H Ditchfield's chapter on the villages around Bath comes a note on houses of the fifteenth century in the Avon valley, by Harold Bialsperr, F S A. The sister city of Bristol is described in outline by George Parker, M D, Wells by R B Reid, and Glastonbury by F Bligh Bond, F R I B A, the Mendip country by Dom Ethelbert Horno, F S A, and picturesque Bradford-on-Avon by C E S Flemming, M R C S. The closing chapter gives short biographical notes on famous Bath residents of the past. The many illustrations, as we have indicated, form a notable feature of this sumptuous volume. They comprise a number of admirable reproductions of water-colour drawings, aquatints, and old prints and portraits from various collections, and thirty-one wood engravings by Horace Gerrard, specially cut for this book during the present year. It is peculiarly appropriate that wood engraving should be chosen as a means of interpreting the old world charm of the buildings and scenery around Bath, and the editorial committee is to be congratulated on securing (to quote its own words) the co-operation of an artist whose work is doing much to revive the growing interest in this old method. Readers who have appreciated examples of Mr Gerrard's art in our pages will find in the *Book of Bath* ample opportunities for studying a treatment of architectural subjects which combines subtlety of insight with breadth and holdness of execution. An exhibition of his work is on view at the Pump Room, on the Roman Promenade Terrace, until July 30th.

LUNCHEON TO OVERSEA REPRESENTATIVES

Following their hospitable custom of the past few years, the officers of the Association and the Chairmen of the Organization and Dominions Committees gave a luncheon party at Fort's Restaurant on the first day of the Annual Representative Meeting in honour of the Oversea representatives who have come to this country to take part in the proceedings in Bath and London. Dr H B Brackenbury, Chairman of the Representative Body, presided, and beside him were Dr W N Robertson, C B D, Vice-Chairman of the Australian Federal Committee (Queensland), Dr J Barcroft Anderson (Representative on the Council for the African group of Branches), Dr R A Bolam (Chairman of Council), Mr N Bishop Harman (Treasurer), Dr S Morton Mackenzie (Chairman of the Organization Committee), Sir Jenner Veirall (Chairman of the Dominions Committee), Dr J A Macdonald (Chairman of the Journal Committee), Dr T D Greenlees (past Representative on the Council of the African group of Branches), Mr W G Mumford (Acting President-Elect), Dr R G Gordon (Honorary Local General Secretary), Alderman Cedric Chivers (Mayor of Bath), Dr A de V Blathwayt (Honorary Secretary of the Dinner Committee), Mr R G Hogarth, C B D (President-Elect for the Nottingham Annual Meeting, 1926), Dr F J Gomez and Lieut Colonel Rait (Representatives on the Council of the West Indian and the Indian Branches), together with the senior officials of the Association and the Solicitor, Mr Hempson. Dr Brackenbury, in proposing the health of the guests, said that these informal occasions helped to get over the difficulty of making personal contact with

Oversea representatives, whom year by year those at home were more and more glad to meet. He compiled with the toast the names of Dr Robertson and Dr Barcroft Anderson, Dr A Davidson (New South Wales), Dr J P Major (Victorian Branch), Dr H Bell Walker (Cape of Good Hope Eastern Province), Dr Murray (Western Province), Mr F C Madden, O B E (Egyptian Branch), Major T J Hallman, O B E, R A M O (Mesopotamia Branch), Dr C E P Forsyth (Assam Branch), and Dr E F Hatton (Grenada Branch). At the Chairman's suggestion each guest rose for a moment in his place at the mention of his name. Dr Robertson, in response, expressed his pleasure in voicing the loyalty of the Oversea Branches, and spoke of the enthusiasm and devotion for the British Medical Association at home manifested by the profession in every place he called at on his journey through Australia this year. He paid a special tribute to Dr R H Todd, whom he described as a tower of strength to the Association in Australia, and a very large factor in its strength and success. He wished also to thank Dr Cox and Dr Anderson for their kindness to himself in this country. As a newcomer to Representative Meetings he admired the excellence of the arrangements and the freedom of discussion. He looked forward to the time when London would take its proper place as the great post-graduate centre of the empire and the world. Dr Barcroft Anderson added his tribute to the central work of the Association. Efficiency on the frontiers of the empire, he said, depended on two things—on the sending out of efficient men from home, and on loyal support at home—and he gave illustrations of the advantage thus derived by the South African medical profession. Dr Davidson and Major Hallman also expressed the most cordial appreciation of their hospitable welcome that day, and of the help given by the parent Association to the Branches abroad. Before the company returned to their labours Dr Brackenbury remarked how gratifying it was to hear by word of mouth from those concerned that the Association was giving real help in the practical work and the day-to-day problems of its members overseas.

THE ANNUAL EXHIBITION

The Annual Exhibition of surgical instruments, appliances, drugs, and foods was held in the Market, High Street, Bath, adjoining the Guildhall. This is roughly a circular building, around which the exhibitors' stalls, to the number of more than eighty, were arranged in three concentric rings. A fountain in the middle, a flower-decked entrance, and other decorative effects completed the transformation of what is ordinarily a bare market hall. The exhibition was opened on Tuesday morning, in the presence of the Mayor of Bath (Alderman Cedric Chivers, J P), by Mr W G Mumford, O B E, F R C S, Honorary Secretary and Acting President-Elect. The Mayor offered his congratulations to the Association on having so vastly improved the City Market, which for some years had been an eyesore. Mr Mumford said that the duty of opening the exhibition devolved upon him owing to the fact that Dr Thomson, the President-Elect, was suffering from illness. Many factors contributed to the success of an Annual Meeting of the British Medical Association, and one of the most important was that of providing a comprehensive exhibition. It should give an epitome of everything up to date in the way of surgical and medical appliances and therapeutic material. The value of such an exhibition was, in the first place, commercial but it was also educational. In the catalogue there were represented the principal makers of surgical instruments and of drugs in the kingdom. He extended a hearty welcome to the exhibitors, who had made so wonderful a transformation of what was a dilapidated old shack, and he thought it

would be a good thing for Bath if the Association could see its way to leave behind the fittings! He expressed thanks to the City Council and the Markets Committee for placing the space at the Association's disposal. The advance of medical science had made such an exhibition a much more complicated matter than it would have been a hundred years ago. At that time, he supposed, the equipment of a medical man could have been placed on a single shelf of one of the stalls. It was a matter for congratulation that the number of stalls—eighty-six—is larger than last year. He reminded the exhibitors, finally, that the value of such an exhibition measured even in commercial returns, was continued for long after the medical visitors had returned to their homes. Among those present at the opening ceremony were the Chairman of the Representative Body and the Chairman and most of the members of Council. The hour of the re-emption of the Representative Meeting was put back in order to permit its members inspecting the exhibits.

There is a very good attendance at the Annual Meeting at Bath, down to midday on Wednesday the number registered was 999.

A CLEAN MILK EXPERIMENT

THE third clean milk competition organized by the Kent Education Committee extended from the middle of January to the middle of April. There were forty-five competitors. Each competitor submitted six samples of milk at fortnightly intervals, and the inspecting judge paid two surprise visits to each herd, taking samples of evening milk on each occasion. The results of the competition showed that a very considerable improvement had occurred in these milk samples as compared with those of the first competition, of which an account was given in our issue of November 3rd, 1923 (p. 831). Thus, while in the first competition 32.4 per cent samples reached the Certified standard and 63.6 per cent the Grade A standard, in the 1925 competition 73.1 per cent samples were classified as Certified and 88.1 per cent as Grade A. Moreover, an increase in the keeping quality of the milk was manifest, the average time before tainting occurred being three days and ten and a half hours in the present competition, and two days and twelve and a half hours in that of 1923. Since the commencement of these competitions several farmers have improved their cowsheds by putting in new windows and providing artificial light, the ventilation arrangements and the floors have also received attention, and the sterilization of the utensils used is now very much more thorough. The inspecting judge in his report drew attention to the great improvement in many farms during the three years. The practical utility of these competitions has been fully demonstrated, they are obviously of no little value as showing the high standard of purity that can be attained in actual practice.

SCIATICA

SCIATICA, the old enemy that lays so many of us by the leg as the years increase, has for long been regarded as generally due to neuritis of the sciatic nerve. The existence of such a sciatic neuritis has always been assumed rather than proved, and where signs of involvement of the sciatic nerve or its sheath have been found absent sciatica has, as a last resort, been attributed to a "neuralgic condition" of the nerve. According to Dr Helweg¹ of Copenhagen, sciatica is not a disease of the nervous system at all but is a myopathy of the posterior region of the leg due to overwork, a functional myopathy. In the vast majority of patients sciatica is due, he thinks to an affec-

tion of the muscles at the back of the leg and in the gluteal and lumbar regions, and is caused by excessive use of the muscles in question. This muscular lesion is the cause of the pain and other symptoms described clinically as sciatica. Dr Helweg would have us dismiss from our minds all ideas of "neuritis" and "neuralgia" when investigating other cases with pains similar to those of sciatica—cases of lumbago, for example, or of muscular rheumatism, myalgia and so on. This novel conception of sciatica is based by Dr Helweg on the results of special methods of palpating the muscle in and about the affected region, the patient lies on his front, care is taken to obtain the best possible muscular relaxation, the surface of the skin is well oiled, and the physician palpates both legs at the same time so as to be able to compare the diseased side with the sound at every point. Both patient and physician must be placed symmetrically and stress is laid on the importance of practice in the art of palpation of the muscles, repeated examinations are often necessary before a positive opinion can be expressed. In all cases of sciatica Dr Helweg finds that larger or smaller sections of the muscles in the gluteal region and the back of the leg feel firm in the affected than they do in the sound leg. As the patient gets better these palpable changes in consistency lessen and tend to vanish, often, however, they have not disappeared completely months after the subjective and the other objective signs of the disease have passed away. Discussing the three cardinal signs of sciatica—namely, pain along the back of the leg, tenderness to pressure along the back of the leg (Valleix's sign), and pain on flexing at the hip the leg already extended at the knee (Lasegue's sign)—Dr Helweg brings forward experimental proofs for his view that they are all best explained as evidences of myopathy rather than sciatic neuritis or neuralgia. It is he says, the affected or hardened muscles that are painful and tender on pressure or extension rather than the sciatic nerve itself. If, for example a tender "Valleix's point" is detected at the neck of the fibula it will be found that the part of the peroneus longus muscle that springs from the head of the fibula feels harder on the affected than on the sound side. The palpatory technique for determining exactly which tissue (skin, muscle, nerve, etc.) is tender in a case of sciatica is set out in detail. Dr Helweg further argues in favour of his view that the muscular wasting and changes in the reflexes of patients with sciatica are satisfactorily explained by the existence of the idiopathic myopathy, a labor to which he attributes the disease. The changes in cutaneous sensibility he puts down to the compression of the sensory nerve branches by the local myopathy, or to the compression exerted on the sensory nerve terminations in the skin by the toughening of the subcutaneous tissues that may be found in connexion with the primary myopathy. The scoliosis often seen in cases of sciatica is described as the result of the instinctive effort to avoid using the affected muscles. Describing cases of the rare so-called "radicular sciatica" recorded mainly by French neurologists, and going through the literature of the subject, Dr Helweg concludes that the term covers a fortuitous association of two different and independent neurological entities in the same patient—namely, a meningo-radculitis and a myopathy both placed so that the sites of their clinical manifestations are the same. Summing up the results of his investigations, Dr Helweg states that in at least 90 per cent of the cases diagnosed as sciatica a myopathy (such as is described above) is the pathological basis of the disease. Sciatica should not be diagnosed in patients who have pain in the regions traversed and innervated by the sciatic nerve but do not show the myopathy or Valleix's or Lasegue's sign. Dr Helweg is perhaps rather too dogmatic, but it would seem to be worth while to remember and test his theory.

A CURATIVE SERUM FOR SYPHILIS FROM THE LLAMA
 The llama, which is used as a beast of burden in South America, is known generally outside its country of origin only as a zoological curiosity. Great scientific interest, however, has recently been directed towards this animal, which alone among the domestic animals has been found to be a carrier of syphilis. *Dr. Jamnaghi and Lamedotti of Buenos Aires* have recently been able to show that the organism in the llama is identical with the treponema of man. Female llamas have been successfully infected from a human sore, while a laboratory accident showed that the llama spirochaete was virulent for man. Syphilis has been endemic in Peru since the days of the Incas, in prehistoric times. A question of great historical interest is thus raised. Was man the infecter of the llama, or was he infected by that animal? The disease in the llama is etiologically and pathologically analogous with human syphilis, but the course is in general shorter. The llama shows all the symptoms that man does, including the cerebral, but the tertiary period usually occurs in about two or three years after the original inoculation. A point of more than academic importance, however, is the discovery of a curative serum for the llama. An animal is given ten to fifteen inoculations with an attenuated culture. The resulting serum has been injected into syphilitic llamas, and has beyond doubt cured them. Animals treated on the appearance of the primary lesions have lived for three to ten years, while the controls have all died from general paralysis in less than three years. In the treated animals the biological reaction remained negative, and their progeny showed no taint of the disease. Remarkable results have also been obtained in the secondary phase. The use of the serum in man has produced results more rapidly favourable than those which have been obtained with the usual chemotherapeutic methods, the serum, moreover, is absolutely harmless. It is too early yet to say how permanent are the results in man and that an absolute cure is obtained, that is a matter for years of experimentation and clinical observation, as *Dr. Jeanselme* pointed out to the Académie de Médecine on March 10th (see *JOURNAL*, March 28th, p. 628). Llamas are now being obtained by the Pasteur Institute for these investigations.

PREDISPOSITION TO INFECTIOUS DISEASES

A PAPER by *Drs. Selma Meyer and Erich Burghard* of the children's clinic of the Düsseldorf Medical Academy on familial attacks of scarlet fever raises the wider question of the susceptibility of the human organism to infectious diseases in general. Every person is a member of a family, a tribe, and a race. As a result of his inheritance he belongs to a family, and owing to the possession of definite characteristics in common with others he belongs to a group of similarly constituted individuals. By use of the method of iso agglutination of the red corpuscles by definite human serums a classification of mankind can be made into four groups, the members of which resemble each other by the possession of this biological feature. This uniformity exists in the case of constitutional anomalies, such as an inferiority of whole groups of tissues, as is exemplified in weakness of the skeletal and connective tissues, and the liability of certain organs to be attacked. A familial predisposition for diseases of certain organs has been rendered probable, not only as regards purely endogenous diseases, but also as regards the character of the reaction to infection. It is alleged that the localization of tuberculosis, syphilis, and diphtheria, the peculiarity of the measles eruption, and the nature of the attack in typhoid fever, tend to be similar in members of one family. The character of the resistance to disease, the supply of immune bodies, and the local

immunity of the portals of entry of infection also, it is said, show the same tendency. In diphtheria the familial predisposition is thought to be exemplified by the simultaneous occurrence and equal severity of the attack, particularly as regards the susceptibility of the nervous system and cardiac muscle to the diphtherial toxin. In this disease the results of the Schick test are usually identical in the parents and children, and so also are those of the Dick test as regards immunity to scarlet fever. It may be mentioned in passing that *Hinszfeld and Brokmann* have recently asserted that susceptibility or immunity to diphtheria, as evidenced by the reaction to the Schick test, is correlated with the particular blood group. *Meyer and Burghard* have made a careful analysis of the cases of scarlet fever in the Düsseldorf children's clinic during the last five years, and conclude that there is not so much a familial predisposition to the disease as a predisposition among members of the same family for certain organs to be attacked. Many families, it is stated, show a high incidence of nephritis, otitis, and other complications of scarlet fever, as well as a similar temperature chart.

GIFT FOR RESEARCH BY THE DUNN TRUSTEES

THE trustees of the late Sir William Dunn have made a donation to the Medical Research Council of £2,000 per annum for a period of five years to be used for the promotion of research work in medicine at the discretion of the Council. The Medical Research Council, in accepting this generous benefaction, has intimated that for the present it will apply this special Dunn Fund in chief part to the furtherance of the organized studies of filterable viruses which it is supporting, and in particular to the recent developments of this work in relation to cancer. *Mr. Barnard, Dr. Gye, and their colleagues*. The Dunn Trustees have made important previous benefactions to the advancement of medicine. They have endowed a chair of pathology at Guy's Hospital, erected a school of biochemistry at Cambridge, and endowed a chair in biochemistry there, now held by *Sir Frederick Hopkins*, they have given a new building for the school of pathology at Oxford, now being erected, and have provided equipment for the school of pharmacology there. They have also built and equipped laboratories for the university medical clinics at St. Bartholomew's Hospital, St. Thomas's Hospital, and the London Hospital.

THE KING has appointed *Sir Thomas Jeeves Horder, Bt.*, to be a Knight Commander of the Royal Victorian Order. *Sir Thomas Horder*, who was knighted in 1918 and created a baronet in 1923, has been physician-in-ordinary to the Prince of Wales since 1923. *Dr. Russell Facey Wilkinson*, who is physician to Prince and Princess Arthur of Connaught, to whom he was medical officer in South Africa, has been appointed a member of the fourth class of the Royal Victorian Order.

THE annual meeting of the Canadian Medical Association at Regina from June 22nd to 26th was most successful, and in connexion with it the annual meeting of the Canadian Medical Protective Association and a meeting of the Canadian Radiological Society were held. *Mr. H. W. Carson, F.R.C.S.*, President of the Hunterian Society of London, who was specially invited through the British Medical Association as the guest of the Canadian Medical Association, delivered addresses on the surgical treatment of gastric and duodenal ulcers and on cancer of the colon. *Mr. Carson*, who has returned to London, tells us that he has come back with the most agreeable recollections of the cordiality of his reception at Regina.

VIRUSES AND CANCER

[At our request Dr Archibald Leitch has written the following article on the report published in the "Lancet" last week (July 18th, p 101), in which Dr Gye has described the present results of his highly interesting researches into certain aspects of the cancer problem]

PYRSON ROUS of the Rockefeller Institute in 1911 reported the discovery in a fowl of a pathological condition in many respects similar to a malignant neoplasm, and by him classified as a spindle cell sarcoma. Thus he was able to transfer to other fowls of the same sort by inoculation of portions of the diseased tissue, by such tissue desiccated, or by filtered extracts from it. The fact that it could be propagated by cell free filtrates placed it in a separate category from tumours proper. In subsequent years Rous found two further examples of the condition, one classified as osteochondrosarcoma, and the other a spindle cell sarcoma of peculiar intracanalicular pattern, both being capable of propagation by filtrates. Other tumours of fowls, recognized as sarcomata, have been described which were not propagable by similar means. Experiments with the Rous-sarcoma, especially the first, have been conducted in various laboratories throughout the world, and controversy has raged from time to time as to the nature of the condition. Many of the controversialists, and chiefly those who had no direct practical knowledge of the experiments, refused to believe that the lesions were sarcomata, or, indeed, tumours at all. In this country one of the tumours, Rous No 1, was studied at the Lister Institute, and for a period of six or seven years at the Cancer Hospital Research Institute by my predecessor, Dr Alexander Paine. The malignancy of the tumour, or (as some would prefer to put it) the virulence of the infecting agent, has increased considerably during the intervening years. The inoculation of the tumour filtrate containing what Rous has simply termed the "agent," produces in fowls a tumour-like condition at the site of inoculation of a rapidly progressive nature, accompanied by the formation in various organs of similar lesions ("metastases"), unattended by any rise in temperature, and bringing about the death of the fowls usually within a month, sometimes within a fortnight. The histological appearances are peculiar and characteristic. Without going into details, I may say that from what I have seen of the disease, clinically and microscopically, I have never been able to convince myself that the thing was a sarcoma. I was not concerned to deny it, I was merely unconvinced. That attitude of suspended judgement is, or was, the attitude of many others. To call it an infectious granuloma did not give us greater consolation. The position was very unsatisfactory.

Now comes the very remarkable and extraordinarily interesting work of Dr W E Gye published in the *Lancet* of July 18th. The Rous-sarcoma No 1 is minced, ground with sterile sand in a mortar, mixed with saline or Ringer's solution in the proportion of 1 gram of tumour to 100 ccm of fluid and filtered through sand and paper pulp. The "sand filtrate" is passed through a close-pored filter and a clear cell free fluid (the "candle filtrate") is obtained, which, when tested on chickens, gives rise to the characteristic disease. In a protocol of one of his experiments he shows that a small dose of the filtrate—for example, 0.01 ccm—produces nothing, a larger dose, 0.25 ccm, slowly produces a tumour whilst 1 ccm brings about a rapid formation. Thus the result corresponds generally with the quantity injected. A certain minimal quantity, possibly varying with different samples, is necessary. Another method of obtaining the active agent—and this is where Dr Gye breaks new ground—is to place a fragment of Rous-sarcoma in a test tube containing 5 ccm of Huxley's bouillon with 0.2 per cent of potassium chloride and 1 ccm of fresh rabbit serum. This is incubated under either aerobic or anaerobic conditions, and the medium is found to be infective returning its infectivity in favourable circumstances, such as the use of a large fragment of tissue and strict anaerobiosis for a week. In less favourable circumstances the infectivity may be lost in two days. We may call this the "primary culture" without for the moment, com-

mitting ourselves to the idea that something has actually proliferated in the serum broth rather than diffused into it from the fragment of tissue. There are thus two ways of obtaining the infective agent.

The "agent," whatever it is, can be rendered innocuous by treating it with chloroform, as Rous showed. Dr Gye's technique is as follows. He grinds up Rous sarcoma with sand as before, adds 100 ccm of Ringer's solution to sand is before, adds 100 ccm of Ringer's solution to 5 grams of tumour tissue—that is, five times the concentration of what is stated above—and filters through paper pulp and sand. Of the clear filtrate so obtained 10 ccm is placed by means of a pipette at the bottom of a tube, taking care not to wet the sides. The tube is slanted and a few drops of chloroform are allowed to run down the sides, some of the chloroform remaining temporarily as a film on the surface of the fluid and the rest sinking to the bottom. The tube is placed in a beaker of water already heated to 37° and incubated for half an hour. Then with a pipette the chloroform globules are repeatedly sucked up and expelled in order to produce a thorough saturation of the fluid with the chloroform. It is again incubated for three hours and the chloroform is pumped off. I confess I do not see the rationale of this particular technique in preference to shaking with chloroform, but doubtless Dr Gye has a very good practical reason for it. A filtrate which was treated with saline instead of chloroform produced Rous sarcoma in doses of 0.2 ccm, whereas another portion of the same fluid treated with chloroform in the manner described failed to infect in doses of 2 ccm—that is, ten times the quantity. Stress is laid on the importance of the temperature and the complete saturation of the filtrate with chloroform for the "destruction of the virus," and Dr Gye cites experiments to show that treatment with chloroform at room temperature or incomplete saturation with chloroform may fail to render the filtrate innocuous. In other words the test, and the only test there can be, of the innocuousness of the fluid is the fact that it fails to produce tumours when injected into the fowls. This it seems to me, is very important.

The "primary cultures," as we have seen, lost their activity—of their own accord, so to speak—in from two to seven days. The explanation of this given by Dr Gye is most ingenious, and on its acceptance and proof depends the value of his subsequent wonderful work. Here give me leave to say that if it be proved beyond doubt to be true as I trust it will be, it will not be merely the extra bit of luck such as in most cases enables a man of science building on the work of his predecessors, to achieve an outstanding success: it will have been a stroke of pure genius. To quote Dr Gye's own words: "From the beginning of this work on the Rous sarcoma I suspected that this loss of infectivity does not depend upon the death of a virus, but upon the disappearance of an accessory chemical factor which governs infection of cells." He inoculated fowls with 1 ccm of a "primary culture" that after three days' incubation had lost its infectivity as shown by the negative results. He inoculated fowls with a similar quantity of the sand filtrate rendered innocuous by chloroform also with negative results. But when he injected a mixture of half the quantities of these two separately inactive materials, Rous sarcoma was produced. The conclusion was that two things are necessary: (1) a virus, and (2) a labile chemical substance, present in the chloroformed filtrate, which in some unknown way renders the cells of the fowl susceptible to the infection by the virus.

Another piece of evidence in favour of the thesis that two separable factors were at work was obtained by taking infective "primary cultures" and subjecting them to centrifugalization for two hours at a speed of 9,000 revolutions a minute. Under favourable conditions, capable of being controlled, the fluid could be divided into two parts, the upper layers containing the accessory factor—a non-particulate chemical substance—and the lower, especially the deposit, containing the virus, which therefore was presumably particulate. It was found to be possible to wash this deposit free from the other factor, so that by itself it produced no lesion on injection, but when recombined with the upper virus-free fluid it gave rise to Rous sarcoma. The experiment was performed on fifteen occasions. Putting aside two of these, as contamination

runned the experiments, Dr Gye succeeded in thirteen cases in obtaining by the washing of the centrifuged deposit a material (the "virus") free from admixture with the accessory chemical substance. This is the obvious result obtained by treating the sand filtrate with chloroform there he obtained, according to his conception, the chemical factor free from virus, here he obtained the virus free from chemical factor. However, in two of the latter experiments, the washed deposit was still infective, though the infectivity was diminished.

In order to obtain a virus which could be thoroughly relied upon as being free from the chemical factor (all the indications, of course, pointing to the existence of a particular virus), he endeavored to cultivate the virus by bacteriological methods. In this he was successful, and by itself it is a great achievement. By successive subculturing from the "primary culture" he could be sure that anything that was propagated in the later subcultures would be a living thing capable of proliferation, for any purely chemical substance would be lost by the successive dilutions. Thus, in the fifth subculture the virus alone would be present. On inoculation into fowls it, of course, produced no lesion, but when added to the necessary chemical factor obtained either by treating the sand-filtrate with chloroform or by taking the meat upper layers of a centrifuged "primary culture" (for both methods were used), the Rous-sarcoma resulted.

Up to this point the work dealt entirely with the analysis of the agent of Rous-sarcoma, and, as I have said, the nature of this disease has been a matter of dispute. Attempts had been made, though lately recorded, by those engaged in cancer research, to obtain from undisputed mammalian cancers something corresponding to the Rous agent, but they had met with no success. Dr Gye, proceeding at first on similar lines, also failed. He employed four transplantable tumours—a sarcoma and a carcinoma of the mouse, and a sarcoma and a carcinoma of the rat—and treating them in the same way as he did when preparing the extract of the Rous sarcoma he was unable to produce a tumour in the appropriate animals with the cell free filtrates. He then tried his second method of obtaining the virus—the "primary culture." Let it be remembered that, in the "primary cultures" previously, both the virus and the accessory chemical factor were present together for a day or two, and only after that the second factor disappeared. Taking the mouse sarcoma (the others were not refested) he placed large portions of it in tubes of his serum broth medium and incubated these under very strict anaerobic conditions. After twenty-four hours' incubation the fluid in the tubes was pipetted off and centrifuged. The upper layers were inoculated into mice, and sarcomata were produced with the same characteristic structure and growth as the original mouse tumour. It is unlikely that any tumour cells remained in the fluid so treated and gave rise to the tumours on inoculation, but to make assurance doubly sure Dr Gye filtered similar "primary cultures" through a close-pored filter and still was able to induce tumour formations. The proof that two factors—a virus and an accessory chemical factor—are concerned here also is reserved for a later communication. Dr Gye suggests that the failure to produce the mouse sarcoma by the direct tumour filtrates is due to the oxidation of the chemical factor when it is being ground up with sand. This is of particular interest to me. In the spring of last year, in searching for the evidence of a "growth substance," which we imagined was produced by our carcinogenic agents, and which possibly corresponds with Dr Gye's "specific factor," I ground up in a mortar mouse tumours of the identical strain (as well as the rat sarcoma) after having frozen the minced tissue with liquid oxygen. I injected the ground up material, in which the cells had been thoroughly disintegrated, intradermally thrice weekly for two months, hoping that this excessive amount of growth substance in addition to the repeated trauma with the needle would induce a neoplastic response on the part of the cells. All the experiments were negative but I concluded that nothing in the nature of a virus could have existed in the tumours, seeing that the whole tumour cells can be subjected to the

temperatures of liquid oxygen and yet give rise to tumours on inoculation. In view of what Dr Gye says, I must have done the very thing necessary to destroy the specific factor. It is probable, however, that the virus remained unaltered and was injected over that long period. It may be mentioned that when, after an interval, I tested the animals with an inoculation of tumour cells, tumours grew in them just as in the controls. There was neither immunity nor increased susceptibility induced. My colleagues, Kennaway and Fry, tried similar experiments with human tumour material, and, in one series, tri-planting was done concurrently with the injections, but the production of optheloma was not accelerated.

Dr Gye's experiments with the mouse sarcoma seem to me to be of the utmost importance. I cannot think of any possible flaw which would vitiate his results. The nature of that particular tumour has never been doubted by any competent observer. It is probably true that no pathologist of experience feels quite so certain of his diagnosis in sarcoma as he does in the case of carcinoma, but here there is little room for doubt.

With the other three rat and mouse cancers mentioned, direct reproduction by cell-free fluids has not been accomplished. Dr Gye adopts an indirect method of demonstrating the virus in them: he substitutes "primary cultures" of them for the Rous sarcoma virus, and by combining these with the accessory chemical factor obtained from the chloroformed filtrate of the Rous-sarcoma, he produces typical Rous-sarcoma in fowls. Finally, a similar procedure was adopted in the case of three human malignant tumours—two carcinomata of the breast and a sarcoma of the thigh. Two of these afforded no evidence of a virus, but the third, a carcinoma, yielded a virus which, along with the chloroformed filtrate of the Rous sarcoma, produced a Rous-sarcoma in fowls. It is remarkable that the chemical factor should be responsible not only for the pattern and characteristics invariably produced. It is not merely a spindle-cell sarcoma of the fowl that is produced, not merely a Rous sarcoma, but a particular variety—namely, "Rous-sarcoma No 1."

We thus have evidence that all these tumours have a common factor—the virus which is probably identical in all cases—and a specific factor peculiar to every tumour—the accessory chemical substance which has such unexpected properties. Under experimental conditions the virus cannot act without the second factor, and this factor so far has been obtained only from existing tumours. But how is this essential factor produced in the animal body? Its formation must precede the formation of any tumour which it helps to originate. There must be some other source for it, and so the greater problem remains. Do our carcinogenic agents bring about the formation of the accessory chemical factor? Hosts of questions arise in our minds, but we must wait the answers in the future. At the present time it is difficult to see how the observations can be put in line with many already known facts.

The paper under consideration is obviously only an instalment. Dr Gye's researches have probably gone much further, and what may seem to be lacunae in the argument may be already filled up. The evidence here given in favour of the presence of a virus in all the mammalian tumours tested, with the exception of the mouse sarcoma, is indirect, and, therefore, not wholly satisfying. Carcinomata have not been produced. Probably the proof of the identity of the viruses will soon be strengthened by demonstration of their unity might be further emphasized, for example, by using the accessory chemical factor from a rat carcinoma, combining it with the virus from a human cancer, and producing a sarcoma in the rat. We shall have to wait in patience for the developments that are possible, but we have had such appetizing fare that we are clamouring for more. In particular, I should like to see more certain that the method adopted by Dr Gye for destroying the virus in the filtrate of the Rous sarcoma is effective beyond doubt. Practically everything else hangs on that. Suppose for a moment that the treatment of the filtrate with chloroform weakened, but did not wholly destroy, the infective agent: what then? It would require

on each and every occasion on which it was used a fairly large number of fowls for its detection, and perhaps only one unusually susceptible bird would show the effect even with a greatly increased dose. Equally, to prove beyond doubt that the infective agent was destroyed, a large number of controls would have to be employed, for it would be too risky on any occasion to depend upon a few. If the destruction of the infective agent is not always assured, then the thesis of the presence of the two factors is considerably weakened: there would be no convincing proof of the actuality of an accessory chemical factor, and the indirect evidence of the presence of a virus in the mouse carcinoma, in both rat tumours, and in the human cancer, which depends entirely on the complete destruction of the Rous agent, might fall to the ground. This is so evident that I cannot imagine it would be overlooked by Dr Gyo, though the point is not considered in his paper. I am very far from feeling that such possible criticism is worth entertaining, in view of the brilliant work that Dr Gyo has accomplished and the merited recognition he has attained.

Scotland.

EDINBURGH CIVIL SERVICE NURSING HOME

AN interesting experiment with regard to the problem of the "pay hospital" has recently been begun in Edinburgh. Many causes have contributed to make the position of hospitals in Scotland unsatisfactory, and the report by the Scottish departmental committee which recently sat to investigate hospital inadequacy is expected with general interest. Many persons are of opinion that there is a great deal of general hospital abuse, both the accommodation of the hospitals and the gratuitous service of their staffs being used by persons who are quite able, individually or collectively, to pay for both. The new experiment is a nursing home which has been acquired by the Civil Service Association, a regular staff has been appointed with retaining salaries, and a schedule of fees has been drawn up, consulting fees and fees for minor operations range from 1 to 2 guineas according to the income of the patient, and the fee for major operations runs up to 10 guineas. It appears to be anticipated that the home will supply the needs of persons with an income up to £800 a year or over. The undertaking has arisen out of a discussion which has been going on in the Civil Service Association for a year or two as to the best means of providing for sickness among the members of civil service societies in the East of Scotland, who altogether number about 6,000. A serious problem which menaces the financial position of the civil servant of the middle or lower grades of the service is that of making provision against the contingency of serious illness occurring in his family. This may involve prolonged residence in a private nursing home, or a surgical operation, and it is felt that it may frequently result in financial embarrassment from which the junior civil servant may suffer for many years. A committee of medical and other experts was brought together to investigate the various possibilities, and found itself faced with the problem of establishing a special hospital. A surgical home of some twenty years' standing came into the market, and seemed to fit perfectly the objects in view, it will be ready for occupation shortly. The general management of the home is to be conducted by a limited company, and members have been enrolled, subscriptions fixed and the necessary capital raised. The company will not work for profit and no portion of the income or property will be paid or transferred by way of dividend or bonus to the members. The entrance fee has been fixed at 10s for men and 5s for women, with an annual subscription of 12s for men and 8s for women. An arrangement has been made with H. M. Treasury by which the annual subscription is deducted quarterly from salaries. Provision is made not only for the reception, maintenance, and treatment of members and their dependants, but the home is to offer similar facilities to "any other person or persons whatsoever." The first meeting was held in Edinburgh on July 16th, when the chairman (Mr H. L. Fraser) announced

that the home had been opened for the reception of patients on the previous day. He spoke for some 1,500 members and other prospective members when he said that the principle of transferring risks of sickness from the financially weak individual salaried member to the broad back of a large membership was sound. It would prove commercially sound in surgery just as it had proved itself to be in fire, life, and other forms of insurance. The dietetic, nursing, and medical services would be of a high standard. A medical team had been selected which, co-operating with the family practitioner, would achieve a very high medical standard, and the scheme would be of value as regarded both consultation and treatment. The plan of providing a definite specialist staff had been criticized, but as a rule the specialist employed for surgery, etc., was not the "free choice" of the patient, but was chosen by the family practitioner. The scheme did not, however, preclude any patient from calling in a specialist not on the staff of the home, provided he paid the specialist's fee. It was no part of the scheme to criticize the fees charged for surgical or nursing home services, for it must be kept in view that specialists had to live, and that a very large part of surgical work was unremunerative or indeed unpaid. Competent authorities had put the proportion of this work done in Edinburgh as high as nineteen cases out of twenty, so that the unfortunate twentieth case must pay not only for himself but for the other nineteen cases. Many nursing homes were handicapped by heavy initial costs and a low rate of bed occupation. It was hoped that this scheme might assist in the solution of both difficulties.

NURSING COUNCIL EXAMINATION

The written preliminary examination for the General Nursing Council for Scotland was held on June 2nd. Candidates to the number of 75 presented themselves for examination in Edinburgh, 277 in Glasgow, 19 in Dundee, 47 in Aberdeen, and 2 in Inverness. The oral and practical part of the examination was held a fortnight later in Aberdeen, Dundee, Edinburgh, and Glasgow, the Inverness candidates attending at Aberdeen for this part of the examination. The results were as follows: elementary anatomy and physiology, 392 entered, of whom 319 passed, hygiene, 374 entered, of whom 329 passed, elementary theory and practice of nursing, 386 entered, of whom 359 passed.

England and Wales.

WORKPLACES

A census volume entitled *Workplaces* has been issued. It is believed to be the first occasion in any country on which statistics of workplaces have been obtained and presented. The inquiry was instituted at the 1921 census for the purpose, as then announced, of furnishing assistance in connexion with the problems of improving the transport facilities (bus, tram, and train) for the working public, of housing, and of continuation schools. The analysis of the daily tides of population between one area and another also provides materials for inferences in regard to the day populations and the limits within which individual populations regularly expand and contract. The statistical equipment hitherto at the disposal of local authorities has been limited to an inadequate knowledge of the sleeping or resident population. The desirability of adopting "workplace" as a basis of a real classification alternative to that of place of enumeration or residence was recognized in the census volume relating to industries published a short time ago. The present volume consists of three tables—the first showing for each urban and each rural area of England and Wales its total population and the number of occupied persons over twelve enumerated in the district, the number of those who work outside the district, and the number of persons travelling to work into the district, the second table carries the analysis further and shows for the more important movements the districts to and from which the latter persons travel, while the third table shows for towns with a population over 20,000 the aggregate of the inward and outward

movement, the net balance of the two movements, and a comparison of the night and day populations of the several towns. As would be expected, the largest total movements are towards the centre of London, the night population of the City of London being raised from 13,709 by a net inward movement of 423,006 persons to 436,715 during the day, the City of Westminster receives a net inward movement of 244,406 persons, the Borough of Finsbury of 65,334, Holborn of 58,513, and St Marylebone of 51,500. Most of the boroughs on the outer boundary show a net outward movement, and the same is true of all the larger towns of Middlesex (except Acton) and of the portion of the other home counties that are nearest London. The effect of these movements results in the City of London having a day population nearly 32 times its night population, while the corresponding ratios for Westminster and Holborn metropolitan boroughs are 2½ and 2½ respectively. Amongst towns with more than 20,000 inhabitants (outside London) the following show large daily changes, the increases being associated generally with industrial and mining centres and the decreases mainly with areas of a residential character.

Increases during the Day		Decreases during the Day	
	Per cent		Per cent
Wallsend	24	Leyton	25
Stretford	22	Hornsey	25
Rugby	17	East Ham	24
Eston	17	Hanwell	23
Hebburn	17	Walthamstow	22
Bedwellty	16	Sutton in Ashfield	21
Chelmsford	14	Edmonton	20
Chadderton	13	Southgate	20
Manchester	10	Newcastle under Lyme	20
Newcastle upon Tyne	8	Castleford	19
Luton	7	Mansfield	15
Derby	6	Eccles	14
Coventry	5	Salford	12

There are even greater percentage variations in smaller towns, though on account of their size the numbers involved are of less significance.

The volume has been prepared in the General Register Office and has been published by H M Stationery Office, price 16s. It can be obtained from booksellers. It is to be regretted that the price is so high.

ARTIFICIAL SUNLIGHT TREATMENT AT HULL

In April, 1924, an experimental municipal clinic for treatment by artificial sunlight was opened at Hull, a tungsten arc lamp having been presented by Dr Percy Hall, a member of the city council, and during the following twelve months 110 patients received treatment. Of 31 patients with severe rickets so treated 19 were much improved and 10 were benefited, in 20 out of 22 cases of slight rickets there was definite improvement. Six wasting babies were treated, all except one being much improved. The medical officer of health reports that the clinic has fully justified its establishment, he now recommends the appointment of a whole-time medical officer and the provision of two rooms for carbon arc treatment, and either two large rooms or a number of smaller rooms for treatment by the tungsten arc and mercury vapour lamps. It is estimated that the cost of the electrical apparatus and of running the fully developed clinic would approximate £1,000, and that an additional £1,000 would be required for furnishing. Last April the Hull Royal Infirmary acquired a lamp for this treatment.

Correspondence.

FOCAL SEPSIS AS A CAUSE OF NEURASTHENIA AND INSANITY

SIR,—The importance of the subject raised by the four papers on focal infection, in your issue of July 4th, as a cause of neurasthenia and insanity cannot be exaggerated.

There is one aspect of the problem that was not referred to and which deserves emphasis. In cases of toxic neurasthenia and early toxic psychosis the treatment of focal infection frequently induces an immediate exacerbation of symptoms which tends to be proportionate to the degree to which treatment causes a temporary increase of the toxins circulating in the blood. Thus no exacerbation need be

anticipated in the treatment of infection of the urinary passages by *B. coli*, little need be expected from the removal of an appendix with a localized abscess, in the case of teeth or infection of accessory sinuses the reaction is generally severe. Enucleation of the tonsils skilfully performed causes very much less disturbance than amputation by the guillotine.

I mention this because I have seen two cases of suicide occur within forty eight hours of dental extractions when a number of teeth were dealt with at one sitting. In such cases the correct procedure is either to extract the teeth at intervals, or, better still, to immunize the patient by an autogenous vaccine beforehand.

This phenomenon of exacerbation of symptoms when a septic focus is attacked is in marked contrast to the effect of other surgical interference or of trauma. Thus a neurasthenic woman may temporarily improve after the removal of a simple fibroid. An early psychotic may appear better after he has broken his leg. The substitution of physical disorder for mental conflict tends to be palliative, except when the degree of shock is severe, or, as I have said, when additional toxins are released into the system.

Another point that was not referred to in any of the papers was the effect of chronic toxæmia through impairment of the endocrine function, notably that of the thyroid. The dullness of the child with septic tonsils and adenoids is largely the dullness of subthyroidism, and there are many similar examples of the effect of focal sepsis on mental function through endocrine disturbance.

Professor Nixon ends his paper with this sentence: "A careful and thorough physical examination is more likely to be fruitful than investigation of the origin of the mental state along psycho-analytical lines." Surely this is an unfortunate way of contrasting the two methods of treatment? It suggests that we must either pursue one course or the other. The truth is that the man who psycho-analyses a patient that requires detoxication is blind in one eye, and the man who thinks that all functional cases are either toxic or incurable is blind in the other eye—I am, etc.,

London W 1 July 7th

H. CRICHTON-MILLER

THE ETIOLOGY OF MALIGNANT NEW GROWTHS

SIR,—There are probably few pathologists in this country who have not already read the most interesting papers on cancer and the ultramicroscopic viruses by Dr Gye and Mr Barnard. The work, moreover, has been widely discussed, and the results and conclusions appear to be accepted as correct by many pathologists.

All, however, who wish well for the reputation of British medical science will be anxious lest an over-enthusiastic reception should blind workers to any possible sources of error which a more considered judgement might suggest ought to be thoroughly probed before a work of this nature is accepted as having been proved to be correct. Nothing could do greater harm to the reputation of British scientists than that they should be shown to be in error, possibly in a year's time, by some worker in a foreign laboratory.

I feel sure, therefore, that both Dr Gye and Mr Barnard will appreciate the desire of some workers to be given a little more information on several crucial points, a satisfactory answer to which would go a long way towards convincing those whose critical analysis of the results leaves them in some little doubt.

In view of the fact that ultramicroscopic viruses will tolerate pure glycerol and to a certain extent ether, is Dr Gye convinced that his chloroform treated filtrate is quite free from the virus or contagion? Might not a small amount of specific contagion be left and be made active by non-specific products, including acids, present in what he believes to be his cultures, in the same way that toxins affect the virulence of bacteria? Can he give us some experiments conclusively disproving this possibility?

How many times has the experiment given in Chart 5 been made and has the result always been the same? Have large quantities of the same treated filtrate only been inoculated, as controls, with negative results?

Have entimes of non cancerous tissue been tested side by side with cultures of cancerous tissue when the same treated filtrate was added in each case?

In making subcultures from his primary cultures have any comparative experiments been carried out with subcultures made after heating the primary culture to such a temperature that any virus would certainly be destroyed? Would a fifth subculture from this fail to be made active by a chloroform treated filtrate which for certain made active the fifth subculture derived from the unheated primary culture? Such experiments giving clear cut results would, I suggest, be considered weighty evidence by most pathologists who may not be quite convinced by the result given in Chart 11.

This investigation of Dr Gye and Mr. Bunnard must have a considerable effect on all investigations at present being carried out on the ultra-microscopic viruses, and it is of great importance to other workers that their own investigations shall be carried along the right lines. I am sure if Dr Gye is in a position to give us the information I have suggested it will be of great assistance to and will be appreciated by those working in other laboratories—I am, etc.,

F. W. TROTTER,

The Brown Institution, University of London.

July 22nd

* * A note by Dr. Leitch stating the nature of Dr. Gyo's inquiry will be found at page 174.

THE SEPARATION OF THE PLACENTA

SIR,—In the JOURNALS of April 4th and 18th the subject of separation of the placenta is discussed by some correspondents. The practice of leaving the placental side of the cord untied is referred to as if the idea was a new one. But reference to Smellie's *Midwifery*, published in 1784, shows that it the practice was recommended by him.

In these days of "meddlesome midwifery" some further remarks of his on the subject of separation of the placenta are well worth quoting.

I find that amongst the ancients and moderns there have been different opinions and directions about delivering the placenta: some alleging that it should be delivered slowly, or left to come of itself; others that the hand should be immediately introduced into the uterus to separate and bring it away. Before we run heifer tails in the case. We find in the common course of labour that not once in fifty nor an hundred times there is any danger more to be done than to receive the child. Some of the ancients have alleged that no danger happens on this account the most part sufficient of itself in such cases it is very rare, perhaps not once in twenty or thirty times that I have occasion to separate as it generally comes down by the common assistance of pulling gently at the funis and the efforts of the woman. I also find that the mouth of the womb is as easily dilated some hours after delivery as at any other time so in my opinion, no ought to go in the middle way, never to assist but when we find it necessary on the one hand not to torture nature when it is self sufficient nor delay it too long, because it is possible that the placenta may sometimes though seldom, be retained several days, for if the uterus should be inflamed from any accident and after birth behind the operator will be blamed for leaving the placenta.

—I am, etc.,

Wellington N.Z. June 1st

WILLIAM YOUNG

DEATH CERTIFICATION

SIR,—In the face of an alteration in the giving of death certificates and the terrifying announcements with regard to premature burial published from time to time, not only in the lay press but also in medical textbooks, would it not be well to lay the subject before the profession for consideration with a view to restoring the public confidence, and for our own reassurance, now rendered somewhat unstable when we reflect upon the fact that death of the whole body is a gradual process occupying a definite lapse of time although the suspension of the vital faculties may appear to be sudden and complete?

For my own part I now find myself to be in a precarious position respecting the certifying of deaths. Some years ago I steadily refused to write a death certificate within twenty-four hours of the patient's death, but in these days of hustle I am generally called upon to certify within a few hours of the demise, and meet with indignant protests if I suggest its being deferred.

Seeing the difficulties connected with the confirmation of

Lancet July 18th

absolute death, I wish to propose that, unless there are reasons to the contrary, the doctor shall inspect the naked body of the deceased the day after the death when more manifest signs will have had time to develop, and, being satisfied, shall certify accordingly.

This arrangement would relieve my own feelings as to unpleasant possibilities and help to abolish the increasing dread that calls for extreme measures to establish the proof of death, otherwise a *post mortem* examination should become the invariable rule in order to still all medical and social doubts and perplexities—and thus I am sure the public will not submit to—I am, etc.,

London July 7th.

JOHN GOOD, M.R.C.S.

* * * Bearing on Dr. Good's reference with regard to tests of the fact of death, a recent communication we have had from Dr. J. William Cook is very much to the point. He wrote: "I am glad to see the new Death Certification Bill compels personal inspection of the corpse by the doctor. I never gave a death certificate, even when the patient had died in my presence, until twenty-four hours had elapsed. When I was in practice I came into contact with two cases of trance. On looking through my cases I find that I had cut through the radial artery about thirty times, yet I have several times met with men in large practices who had never seen this done, and were much obliged by being taught the little manoeuvre which means so much to anxious relatives." In response to our request Dr. Cook has given the following particulars: "Straighten the arm, pull back the hand, feel the outer edge of the tendon of the flexor carpi radialis. Make a narrow bladed sharp scalpel, put the point into the skin edge towards fingers, push home to the bone, cut towards the fingers for about an inch, turn the edge outwards keeping the point on the bone, cut upwards and outwards, the gaping mouth of the cut artery should appear at the bottom of the incision. There are generally a few drops of thin venous blood from the venae comites. Dry with a swab of absorbent wool. Place a double layer of lint over the incision and put a band of 1" wide white rubber plaster round the wrist over this. It takes a minute and leaves the body tidy. If the sleeve of the shroud is pulled down nothing is to be seen. It is by taking pains, even in small matters, that one keeps that confidence without which one can do but little with patients. I specially is this necessary in the circumstance of death and of its possibly being only apparent."

ROYAL NAVAL VOLUNTARY RESERVE

SIR,—May I ask your assistance in calling the attention of the younger members of the profession to the attractions offered by service in the Royal Naval Volunteer Reserve?

The R.N.V.R. consists of seven divisions—London, Scottish, Tyne, Mersey, Bristol, Sussex, and Ulster. The establishment provides for 205 medical officers, of whom 50 are on List I and the remainder on List II, and in addition 28 dental surgeons. Each category has to serve twenty-eight days at sea during its first year of service, and subsequently fourteen days biennially, either afloat in one of His Majesty's ships or in a naval hospital or depot. Those on List I have, in addition, to attend periodically at the headquarters of the division to which they are attached for the examination of recruits and other medical duties. The age of entry is from 21 to 32 years. Provision is also made for the entry as surgeon subalternants of students from 19 to 26 years who have passed their intermediate examination in anatomy and physiology. Promotion is on the same basis as in the Royal Navy, except that no examinations are held. During training medical officers receive the naval pay of their rank, and £50 is provided for the expenses of uniform on joining, or, in the case of probationary officers, on confirmation in rank.

The service affords a unique opportunity for seeing the life of the Royal Navy, as well as providing every two years a most interesting experienced free of all expense and well paid for the duties required, whether afloat or ashore. Applications for commissions should be addressed to the Commanding Officer at the headquarters of the nearest division, from whom full particulars can be obtained—I am, etc.,

H.M.S. President Victoria Embankment EC 4 July 13th

J. BRUCE ROBERTSON,
Surgeon Commander R.N.V.R.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT]

THE House of Commons has this week taken the report stage of the Widows', Orphans', and Old Age Contributory Pensions Bill and has debated the Estimates for the Post Office and for education. On Friday the House was asked to advance a long list of smaller bills, including the Therapeutic Substances Bill and the Diseases of Animals Bill, but the Public Health (Scotland) Bill will probably not be taken till the autumn.

The second reading of the Bethlehem Hospital Bill was down for July 21st, and a compromise between its promoters and the local authorities had almost been reached on that day. Legal difficulties supervened, however, and the bill was put back till July 24th. It has already passed the House of Lords.

The medical members of Parliament who went to Switzerland to examine M. Spruhler's methods resumed their conversations with him on July 22nd at the House of Commons. Down to that date their negotiations had no definite result.

Mr H. A. L. Fisher has been chosen chairman of the Select Committee on the Nursing Council, which was summoned to meet and hear evidence on July 22nd.

Bovine Tuberculosis Compensation for Slaughter

Moving a resolution authorizing the payment of money by Parliament towards the compensation of local authorities for slaughtered cattle when tuberculous or suspected of tuberculous, the Minister of Agriculture, Mr Wood, said the Milk and Dairies Act, which prohibited the sale of tuberculous milk and indirectly compelled the slaughter of tuberculous cattle, would come into operation on September 1st. It was impossible for it to operate unless accompanied by a Compensation Order. It was estimated that the gross compensation would be about £67,500 and the Exchequer's share £50,000. The cost of administration would be offset by salvage. Power was being taken to exclude cattle from Ireland which were tuberculous. Great progress had been made in the last few years in getting rid of the tuberculous cow. Nearly 200 herds of dairy cattle in England were completely free from tuberculous. The problem must be tackled on national lines. Many large municipalities spent money in tracing tuberculous among the dairy cows which supplied those areas with milk. But municipal expenditure was largely wasted because when a tuberculous cow had been traced the owner often sold the animal, with the result that tuberculous meat might pass into human consumption, or else the animal was passed to other dairy farmers and all traces of it was lost. The new policy of compulsory slaughter and compensation had been approved by the National Farmers' Union.

Mr A. V. Alexander promised the support of the Labour party for any efforts to reduce bovine tuberculous. Some members were very concerned about the use for human consumption of carcasses of animals which had been condemned for tuberculous. The butchers were concerned because the Order did not arrange to compensate them for any animals which might be condemned after slaughter.

Mr Wood, replying, said it was estimated that 12,000 cattle a year would be slaughtered under the new Order. He could safely say that at present no meat liable to prejudice the health of the consumer was allowed to be sold, but infection could be carried by hides, offal, and other parts of the carcasses used for purposes other than food.

The resolution authorizing payment of compensation was approved.

On the report stage, the Minister of Agriculture said that the carcasses of animals killed under this Tuberculosis Order would be submitted to the public health authorities, as were all other carcasses of animals intended for human consumption. The meat inspection service was in charge of the medical officers of health who were solely concerned with the consideration of human health. No meat that had been inspected and found unfit for human consumption would ever be passed.

The resolution was carried and the second reading of the Diseases of Animals Bill was subsequently taken. Dr Vernon Davies asked the Minister of Agriculture what evidence he required before slaughtering cattle that the case was one of tuberculous.

Mr A. V. Alexander said the Labour party was not satisfied with the Minister of Agriculture's assurance that no actually tuberculous meat unfit for human consumption would ever be passed. They had evidence that in many places the remains of carcasses which had been condemned reached certain classes of the population for human consumption. They were told that there was difference of opinion among medical men as to whether it was actually harmful to the human body to eat of a carcass which had not shown on the post-mortem examination of tuberculous.

Sir Richard Luce said the form of tuberculous which might be absolutely local. The muscle of the body was rarely infected with tubercle. Cows suffering from tuberculous of the udder were the class of animal which it was most important to destroy because they were the most potent source of tubercle to children, but the rest of their carcasses might be entirely free from tubercle and innocuous.

Dr Fremantle thought the danger pointed out by Mr Alexander was serious because of the backward state of butcher's marketing, and veterinary inspection. Although he believed the

bill necessary, he thought the Ministry of Health should go forward at the same time with the control of butchering animals and better veterinary inspection. It was possible that tubercle would show itself in one or two glands only. Those who wished to sail near the wind would strip the meat from near the gland and sell the carcass as sound. Under the present system of scattered little slaughterhouses, proper inspection was not possible. If the consumption of meat slaughtered in the circumstances he had mentioned were allowed at all it should be under the strictest regulations.

Mr Palin said that although the carcass might be free from infection in a case of tuberculous of the udder, the animal was very emaciated. He had frequently known cases where the veterinary inspectors had prevented the sale of this meat in Bradford, and it had been immediately taken to some other place for sale.

The Minister of Agriculture said he did not doubt that the local authorities did their duty. If there were any chance of meat prejudicial to health passing into human consumption he would be willing to try in conjunction with the Minister of Health to take effective steps to stop it. Pigs were not covered by the bill, but could be slaughtered under Meat Inspection Orders.

The bill was read a second time.

Therapeutic Substances Bill Second Reading

Mr Neville Chamberlain moved the second reading of the Therapeutic Substances Bill sent down from the House of Lords, and dealing with the standardizing of vaccines, serums, toxins, antitoxins, antigens, and particularly of insulin. These substances could not be tested chemically, and practically all other civilized countries had an official standardization of their purity and potency, but we had no standardization for our own manufactures, and preparations which had failed to pass the test in foreign countries might be imported here. The Ministry of Health proposed that no one should be allowed to manufacture these substances without a licence and that the import of these substances should not be permitted except under proper standardization or compliance with conditions laid down. A joint committee would be set up to make regulations and to prescribe standards and tests.

Sir Richard Luce said that in accepting the bill the House would have medical and scientific opinion behind it. The bill proposed an Advisory Committee of representatives of scientific and other bodies, but not comprising a representative of the body of general practitioners. He hoped at least one representative of them would be added possibly to be nominated by the British Medical Association. It was desirable that the bill should permit substances to be admitted to this country which were recognized in foreign countries as being of a proper standard without necessarily a complicated standardizing of the substances in this country.

Colonel Sinclair noted that the bill would apply to Northern Ireland, and said it was very important that extracts of organic glands should be subjected to physiological or chemical tests by recognized authorities. Pituitrin for instance was a very potent substance, and it was possible that a practitioner using a particular brand might be accustomed to its effects, but might in an emergency have to use an inadequately standardized brand which was stronger than the brand with which he was familiar. The use of pituitrin of unknown strength might cause the rupture of a wound through overstimulation. Similarly, preparations of insulin might be altogether too strong for ordinary use.

Dr Vernon Davies thought that the bill would have to be altered in committee so that a serum which might be produced abroad and have certain special qualities could be brought in under licence, but not with all the restrictions imposed by the bill. He had in mind one special serum which would not be allowed into this country if the bill became law. Another remedy which might be called a secret remedy, had been largely used for asthma, he was told it was almost impossible to analyse it.

Mr Alexander said the Labour party approved the bill and would help to expedite its passage.

The bill was read a second time and sent to a committee of the whole House.

Mr Baldwin announced that the Government would ask the House to take the committee stage of the bill on July 24th.

Summer Time Bill.—On the report stage of the Summer Time Bill, Dr Graham Little said that the British Medical Association in 1923, and the Society of Medical Officers of Health in 1921, 1923, and 1924 had passed resolutions declaring that summer time was beneficial. He appealed strongly for full six months of summer time and emphasized the importance of additional fresh air in the lives of the people. Mr Cooper Rawson said they could not shut their eyes to the fact that the British Medical Association and its branches all over the country were strongly in favour of the six months period. Teachers all over the country also testified that summer time had been of inestimable value to the children's health. Eventually an amendment was accepted postponing the commencement of summer time to the third Saturday in April, and the bill was then read a third time without a division.

Unregistered Midwives.—In reply to Mr Bennett, Mr Neville Chamberlain, Minister of Health, said that he had received many representations from local supervising authorities and other bodies in favour of the elimination of unregistered midwives, and was himself in favour of it. He did not anticipate difficulty in obtaining an adequate number of registered midwives. He had it in mind to deal with the matter in a bill to amend the Midwives Act which he proposed to introduce as soon as other commitments allowed.

National Health Insurance—Answering Sir Henry Cautley, Mr Neville Chamberlain said that in accordance with a decision of the National Health Insurance Joint Committee, approved societies had been recommended not to allot out of their surpluses on a valuation extra cash benefits in excess of 5s a week for sickness benefit unless they were also making reasonably adequate provision for treatment benefits. In reply to Colonel England Mr Chamberlain said that the proposal that maternity benefit should be administered by local public health authorities was within the purview of the Royal Commission on National Health Insurance whose report he proposed to wait. In reply to Colonel Day, Mr Neville Chamberlain said that an approved society under the National Health Insurance Act was entitled to devote part of its disposable surplus on valuation to making payments towards the cost of providing nursing for its members and might also make subscriptions or donations from its benefit fund for the support of district nurses. There was not, however, any provision in the Act for making payments for the specific purpose of securing the attendance of midwives on insured women at confinement and before considering the desirability of amending legislation in this direction he must wait the report of the Royal Commission on National Health Insurance. On July 20th, Sir King ley Wood (Parliamentary Secretary Ministry of Health) informed Mr T Williams that for the purposes of the second valuation approved societies and branches were divided into two groups to be valued respectively at December 31st, 1922, and December 31st 1923. These arrangements were agreed to by the Consultative Council and were found to be necessary to avoid either a considerable increase in the number of the valuers and their staffs or alternatively a prolongation of the period between the date of valuation and the commencement of the additional benefits.

Ophthalmic Benefit—Asked to explain the difference between the optical treatment previously allowed as an additional benefit under the Health Insurance Acts and the ophthalmic treatment now allowed Mr Neville Chamberlain said an insured person was now able to obtain the advice of an ophthalmic specialist when his medical practitioner thought it was required. Previously there was a doubt whether this could be done.

Doctors and the Telephone—During the debate on the Post Office Estimates on July 20th references were made to the desirability of better telephone facilities for summoning doctors. Sir Robert Hamilton said it would be of inestimable advantage if the inhabitants of such islands as Papa Westray with over 150 inhabitants but no doctor, were able to communicate by telephone with a doctor not necessarily that he should cross but that he should send by telephone instructions as to how the patient should be treated. Major Price said that in a village in North Pembrokeshire two accidents occurred when the telephone wire was down. The nearest doctor was eight miles away and there was a lapsed of eleven or twelve hours before the doctor could get to the county hospital to which the patients had been taken. Mr Buchanan suggested that telephone kiosks in the working-class districts of towns would be of value for getting into touch with the doctor, especially in maternity cases. Colonel Henegge said that in many Lincolnshire villages the only way of summoning a doctor was by sending a cyclist for him, and a great deal of unnecessary suffering was caused. The Postmaster General Sir William Mitchell Thomson said new rural telephone exchanges were being opened at the rate of twenty a month. It might later be possible to provide communication by wireless telephony between the islands in the Orkneys and Shetlands.

University of London—On July 20th Mr Guinness told Dr Little that the Senate of the University of London had declined the offer of April 1920 made by the then President of the Board of Education, of the Bloomsbury site. The Treasury had already informed the Senate of its willingness to consider any preferable alternative proposal for an increase without undue cost of the accommodation for the central offices of the University which the Senate felt able to suggest.

Notes in Brief
No precise information is available of the number of employed persons in Great Britain who are not insured under the National Health Insurance Acts, but 1,300,000 is suggested as a rough approximation.

The Royal Commission on National Health Insurance is considering whether dental benefit should be made statutory under the Health Insurance Act.

At an early date the Home Secretary intends to introduce legislation to remedy defects in coroners' inquiries in murder cases.

The following have been received as teachers of the University of the subjects and at the institution indicated

St. Bartholomew's Hospital Medical School—Dr G Graham (medicine)
Mr H J G Boyle (anatomy)
Westminster Hospital Medical School—Mr Donald H Interson (lecturer of children) Mr Stanley Dodd (obstetrics and gynaecology) Mr Stanford Cado (surgery)

St. James's Hospital—Dr James S Collier (neurology) Dr Robert H Cole (psychological medicine) Dr William H B. Soddart (psychiatry)

The annual report of the Superintendent of the Brown Animal Sanitary Institution for 1924 showed that the number of animals brought to the institution was 4,855. Five lectures on modern bacteriological technique had been delivered by the Superintendent at the Royal College of Surgeons in December 1924 as required under the will of the late Mr Brown. During the year Dr J W used the laboratories to carry out a histological investigation of tuberculous tissues and Dr Shaw did some experimental work on immunizing a sheep to cancer. Mr Ivor who has been reappointed superintendent of the institution for one year from June 1st 1925 had continued his work on ultramicroscopic virus-matter.

reappointed Director

has been elected

Applications for the William Julius Noel Fellowship must be sent to the Principal Officer by October 1st. It is of the value of at least £200, and is awarded annually by the Senate to a graduate of the University who in its opinion has done most to advance medical art and science within the preceding five years and therein shown conspicuous merit.

UNIVERSITY OF BRISTOL

The following candidates have been approved at the examination indicated

Second M.B. Ch.B. (Part I)—J S Adamson A C Price N L Price

MANCHESTER

The Dickinson Travelling Research Scholarship in Medicine has been awarded by the trustees of the Manchester Royal Infirmary to Dr Raymond Williamson and Dr Leslie J Wits of Manchester.

NATIONAL UNIVERSITY OF IRELAND

At a meeting of the Senate on July 10th resolutions of condolence with the relatives were passed on the deaths of Professors Edmund J McWeeney and Henry Corby.

The results of the recent summer examinations were considered and passes honours etc. were awarded in connection therewith. A report from Dr Denis J Coffey, representative of the University on the General Medical Council upon the proceedings of the session of the Council (summer, 1925) was considered and approved.

A new statute (Stat. XXX NUI) was made instituting a lectureship in obstetrics and a lectureship in gynaecology.

Obituary

HAMILTON DRUMMOND, M B, B S Durr
FRCS Ed., MAJOR R A M C (T),
Honorary Surgeon, Royal Victoria Infirmary
Newcastle upon Tyne

The tragic death of Hamilton Drummond, on Saturday, June 27th, as the result of a motor-car accident, came as a profound shock to everyone, for up to the time of its occurrence he was in his usual good health and overflowing with buoyant spirits. For a week he had been in training with the Northumberland Yeomanry, his old regiment, and those who knew him best will realize that he entered whole-heartedly into both the work and the play of the camp, taking his sick parade every day at 6 a.m. and enjoying all the evening functions to the full. On the day of the accident he set out to drive a motor into Newcastle in the early afternoon, accompanied by a couple of orderlies, who occupied the rear seats. There can be no doubt that he was very, very tired when he started on that fatal journey, and somehow the car swerved, ran into the ditch and overturned, and he was pinned beneath. When extricated he was quite conscious, but was obviously seriously injured. The left leg was almost torn off just below the knee, and there were also injuries to the head and trunk. Very soon after the accident he was seen by one of his own colleagues who happened to be driving that way. Though suffering profoundly from shock his first inquiry was for the orderlies who were with him in the car, and next some instructions about his dogs left behind at the camp. He insisted on looking at his leg, and at once recognized that amputation would be necessary. As promptly as possible he was brought to Newcastle to his own private hospital, but his condition became rapidly worse. He was just able to recognize his father before unconsciousness came over him, and death occurred the same evening.

Hamilton Drummond was just 43 years of age. He was the son of Sir David Drummond, CBE, MD, Pro-Vice-Chancellor of Durham University, President of the University of Durham College of Medicine, and a Past-President of the British Medical Association, and brother of Dr Hensley Drummond, one of the honorary physicians to the Newcastle-upon-Tyne Infirmary. He received his early education at Charterhouse, and was a student in medicine in the Newcastle school and at the London Hospital. He graduated MB, BS Durham in 1906, and took the Fellowship of the Royal College of Surgeons of Edinburgh in 1912.

As a medical student he was recognized as a steady worker who acquired knowledge not too easily but always surely, and faced examinations as uncomfortable ordeals. In consequence he started with a thoroughly sound knowledge of his profession. After obtaining his degree he acted as house surgeon and house physician at the Royal Infirmary, Newcastle. After holding these house appointments he went to London, where he acted as clinical assistant and later as house-surgeon to St Mark's Hospital for rectal diseases, and then as clinical assistant to the Great Ormond Street Hospital for Sick Children. While in London he found time to visit most of the great hospitals and the important museums. On returning to Newcastle he was appointed surgical registrar at the Royal Infirmary, and he revelled in the opportunity which this post gave him for clinical work and for the study of morbid anatomy and pathology. Though not gifted with a capacity for artistic representation, he made great use of rough drawings for elucidating his notes,

and the case records of that period are replete with striking diagrams which will always recall Hamilton Drummond to those who knew him as registrar. His house surgery in Newcastle was in the service of Professor Rutherford Morrison, and he subsequently became one of Professor Morrison's private assistants, thus continuing an association which had a notable influence on his career and which was undoubtedly of great mutual advantage.

At the outbreak of the European war Hamilton Drummond held a commission as a combatant officer in the Northumberland Yeomanry, but was at the time actually in the United States, where he had been visiting some of the American hospitals in company with Professor Rutherford Morrison and Mr D'Oyly Grange, now of Harrogate. During the trip Hamilton had been seized with appendicitis and was operated upon by Professor Morrison. After a rather exciting Atlantic crossing he reached home safely and was very soon with his regiment in France helping to uphold the fine traditions of the Northumberland Hussars. He was present at the first battle of Ypres and at Neuve Chapelle, and saw much severe fighting, being several times mentioned in dispatches.

After a time it was recognized that the services of such a competent surgeon could be ill spared, and he was transferred to the R A M C. From then onwards he was always in a forward hospital, and did excellent service, especially in the early treatment of abdominal wounds. It was while thus occupied that he carried out much important experimental work on animals, and, apart from the results, this in itself was a wonderful achievement considering the distractions and embarrassments of that anxious time. The results of this experience were embodied in a series of papers—"A clinical and experimental study of three hundred wounds of the abdomen," written in conjunction with Captain (now Professor) John Fraser, "Ulceration of the colon in the neighbourhood of gunshot wounds," with Captain J S Dunn, "Rupture of the small intestine into the mesentery, the result of indirect violence of a missile," and several others. In addition to his abdominal work he took part in developing the conservative treatment of early gas gangrene by the resection

HAMILTON DRUMMOND
(Photograph by James Bacon and Sons, Newcastle upon Tyne)

of infected muscles, and reported a series of cases jointly with Lieut Colonel C H S Frankham and Captain G E Neligan in the BRITISH MEDICAL JOURNAL. He also reported on the treatment of recent gunshot wounds with bipp, which had just been introduced by his old teacher Professor Rutherford Morrison, and on the treatment of a series of recently inflicted war wounds treated with flurine, and another series in which proflurine was used. This and much other work was cheerfully undertaken in addition to the often very heavy routine. With all this he kept up a constant correspondence with many friends at home, and when on leave was one of the most cheerful men that anyone ever met. Towards the end of the struggle his health gave out and he was invalided home, but after many months on his back he gradually recovered, and was apparently completely restored.

It is a source of gratification to his very many friends to know that the value of his work was fully appreciated by the consulting surgeons, who often expressed their high opinion of his ability both as a practical surgeon and as an investigator.

After the war he was appointed assistant surgeon to the Royal Infirmary, Newcastle, and for five years he served in this capacity, being attached to the wards of Mr A M Martin, who always found him a valuable, loyal, and stimulating colleague. Only three weeks before his death he was unanimously appointed full surgeon to the Newcastle

Royal Infirmary, and his trip to the annual camp was so to speak, his way of a holiday before taking up the full charge of his new work.

At the time of his death he held multitudinous appointments, for he was consulting surgeon to the War Memorial Hospital at Haltwhistle, to the Tyne-mouth Victoria Jubilee Infirmary at North Shields, to the Princess Mary Maternity Hospital, to the Poor Law Hospital at Cateshead, and was also surgeon to the Cripples' Home at Gosforth. These appointments were no sinecure, for he made regular visits, which often involved long journeys into the country. In addition he was demonstrator of surgical pathology and of operative surgery at the Durham University College of Medicine. With all this work in hand he found time to take an active interest in the work of the medical societies, and especially in the Proctological Subsection of the Royal Society of Medicine, and he frequently took part in discussions, both at home and in London, so recently as last May, together with Dr Gilbert Scott, he introduced a discussion on the value of x rays in the diagnosis of diseases of the colon. He was also secretary to the honorary staff of the infirmary, and took his share of committee work of various kinds. Gross pathology always interested him, and in its study he wandered into many fields, and he was often at his best in the informal surroundings of our pathological club when demonstrating some specimen which he had obtained from a post-mortem examination, perhaps on a favourite dog, or a find made during the dissection of an otter or a stray pigeon!

Though writing was never easy for him, his habit of recording and storing his observations gave him ample material on which to draw, and of this he made good use, as his numerous publications show. His first paper was a little note on "Gall-stone formation round a catgut suture," which was published in the *Lancet* in 1908, it was very characteristic, and showed his inquiring nature. The patient had been operated upon previously, and when subsequently a large stone was removed Hamilton bisected it and found the remains of a catgut suture. One can picture him saying, "I wonder what's inside that stone, just let us have a look," and that was his invariable attitude. Altogether he was responsible for some forty-five papers, some of them jointly with his brother officers, and two or three with Professor Putherford Morison. He collaborated with Chad Woodward in writing the excellent article on "Burns and scalds" in Choyce's *System of Surgery*, second edition, and he himself was responsible for those on "Vascular surgery" and "Operations for stricture of the rectum (non-malignant), haemorrhoids, fistula in ano, prolapse" in Carson's *Modern Operative Surgery*.

The main characteristic of Hamilton Drummond was the sportsmanlike way in which he enjoyed both his work and his play. He was full of spirits, and in whatever he did, however arduous or disagreeable the task, his good nature would show itself unfailingly. Though he often appeared to be a little shy and retiring, he was of a most lovable disposition, and whoever came in contact with him could not fail to notice this side of his character. The human side of his work was of great interest to him, doubtless an inherited characteristic, as those who know his father will recognize. The affairs of his patients were his affairs, and if the patient happened to be a gamekeeper or a countryman of any sort, that in itself was a claim to his particular consideration, and before long they would be fast friends. It will never be known how many little acts of kindness and attention he was really responsible.

He loved the country, and no part appealed to him more than his own Northumberland. In field sports he was an adept, and there were none, from deer-stalking to falconry, that he had not essayed. At one time he kept a falcon, and attempted to train it to strike its quarry, and often and often have I seen him gaze for long on those wonderful hawking pictures by Ansdell. Even on active service every opportunity for healthy sport was utilized, and a brother officer writes "I shall never forget the days we spent together hunting the hare close behind the line." Though a good shot, I think above all he most enjoyed a day with the foxhounds, and not long before he died and when contemplating amputation, he

said, "Well, I suppose this means no more hunting." But it was really the life of the open air and the felt that attracted him, for he was a true naturalist, and would study animal life with infinite patience.

When in London he often used to pay a visit to the Zoo, and it was a great treat to accompany him, for he always pointed out something not generally noticed. All the shops where animal skins for sale appeared led a detour in order to pay by a taxidermist. He was a delightful travelling companion, and fellow members of the Club will cherish the memory of the visits to Italy, to Holland, and in the spring of this year to Paris in his company, just as the three friends who accompanied him to and from the meetings of the Association of Surgeons in Dublin will treasure the recollection. Though Hamilton Drummond could not be looked upon as robust, he was very wiry and full of energy, but there can be no doubt he frequently overtaxed his strength.

He was a careful diagnostician, possessed of sound judgement, and a good operator, while he was always painstaking about the after-care and after-history of his cases. In surgical practice he had already made a great reputation, and his service were much sought after, so that his death is a serious loss to the people of the North of England among whom he lived and worked. As a teacher he concentrated on the essential, and was painstaking and impressive.

The funeral was a fitting tribute to this happy boy who off in the full tide of a useful and joyous life, and with the prospect of a wonderful future before him. Seldom has so large a gathering been seen, and seldom too has there been such an admixture of young and old among the mourners. The day was brilliantly fine, and one could not help picturing Hamilton remarking on the "topping" day with that firm look in his eyes that took him to the Northumberland moors he loved so well. The interment took place at Jesmond Old Cemetery. Canon Wilkison, who had known him all his life, and the Rev J. S. C. Farquhar, chaplain to the Northumberland Hussars, and an old schoolfellow, conducted the burial service. None who were present will ever likely to forget the extreme pathos of that last parting at the graveside.

Hamilton Drummond was unmarried and was devoted to his parents. All will share in the most sincere sympathy for Sir David and Lady Drummond and for his brother, Dr Horsley Drummond, and the other members of the family. His numerous colleagues are also to be pitted in that they have lost a most loyal member of the hospital staff who was never known to say an unkind word of anyone.

G. G. T.

We are indebted to Mr. Rutherford Morison, consulting surgeon to the Royal Infirmary, Newcastle-upon-Tyne, for the following tribute to Mr. Hamilton Drummond.

The tragic death of Hamilton Drummond consequent on a motor-car accident on June 27th is an irreparable loss to the infirmary and medical school of Newcastle-upon-Tyne. He was an all-round sportsman with surgical genius.

Tall, thin, and of a strikingly refined appearance, he could not fail to attract attention in any gathering, but was at his best in the country or in the operating theatre. In the country he roamed, shot, fished, played tennis or golf, or cricket, or danced, and did all well. His love for and understanding of animals and of natural history seemed to have been born with him, because even as a boy he was an interesting and instructive companion on any country walk.

In the operating theatre he was an original and thoughtful surgeon, enthusiastic in all his work, a skilful, unflinching operator, and a distinguished pathologist. Shortly before his death, at the age of 41, he was appointed, in opposition to the Royal Victoria Infirmary, and was universally recognized as one of the leading young surgeons of this country.

To superficial observers he often gave the impression of being casual or possessed of a genial cynical humour, but these were chiefly cloaks for his natural shyness and modesty. I now very well that the only thing he would have wished me to say of him is that he "played the game." He did.

Medical News.

The Fellowship of Medicine announces that a vacation post-graduate course will be given at the Prince of Wales's General Hospital, Tottenham, from August 31st to 15th. Sessions will be held each day from 10.30 a.m. to 5.30 p.m., including morning and afternoon demonstrations, and at 4.30 p.m. daily a clinical lecture. On Saturday mornings demonstrations will be given at the North Eastern Fever Hospital and the L.C.C. Mental Hospital, respectively. A similar intensive course has been arranged at the Queen Mary's Hospital, Stratford, from August 24th to September 5th, a special lecture being given on gynaecology and obstetrics. Courses have also been arranged at the West End Hospital for Nervous Diseases from July 27th to August 15th, with special lectures and clinical demonstrations daily at 5 p.m., and in urology at the St. James's Hospital throughout August. Further information may be obtained from the Secretary at No. 1, Whinpoole Street, W.1.

ARRANGEMENTS are being made to hold an international medical congress of industrial accidents and trade diseases at Amsterdam, from September 7th to 12th. The subjects introduced by British delegates include the legal aspects of accidents and sickness, pneumoconiosis, and work in hot and damp atmospheres. Visits will be paid to Rotterdam, Scheveningen, and Leyden, and excursions are being arranged. The honorary president of the British Executive Committee is Sir R. Do Marces van Swinderen, Netherlands Minister to Great Britain, the president is Sir Thomas Oliver, who is contributing a paper on the achievements of industrial legislation and hygiene, and the honorary secretary is Dr. H. Winko, 2, Grosvenor Gardens, Cricklewood, N.W.2, from whom a fully detailed programme may be obtained.

HIS MAJESTY THE KING has graciously consented to accept a copy of the *Iconography of Andreas Vesalius*, by Mr. M. H. Spielmann, F.S.A., which, written to celebrate the quarter centenary of the great Belgian anatomist, at the invitation of the great academic institutions of Belgium, is dedicated by permission to the King of the Belgians, and is published from the Wellcome Historical Medical Museum as No. 3 of the Research Studies in Medical History.

The report of the Shanghai Christian University Medical School for the year ending June 30th, 1924, includes an account of the amalgamation with it of the North China Union Medical College for Women, co-education is resulting in economy of administration and in increased teaching efficiency. Twelve missions now co-operate in the school, and more Chinese proportionately than foreigners have been added to the teaching staff since 1916. It is hoped to increase soon the size of the hospital from 110 beds to 200 or more, and to erect a special building for lepers.

The annual report of the Council of the Royal Society of Medicine states that the number of members is now 4,000 or 400 more than in the first year of the war. Some 20,000 readers were of the library during the year, and 13,000 books were borrowed. About 3,000 books are added to the library yearly. The financial position is stated to be satisfactory, and a committee has been appointed to study the printing and publishing of the *Proceedings*.

The Council of the Chartered Society of Massage and Medical Gymnastics has decided that after the examination for certificates in June to July, 1927, examination in massage as a separate subject shall cease, exception being made in the case of blind candidates and candidates from the services, the present conjoint examination, including medical gymnastics, will be substituted. A new register of members of the society, containing over 5,400 names, has been published (price 4s. 6d.) and may be obtained from the Secretary at 157, Great Portland Street, W.1. The certificate of the society is only awarded after the candidates have received definite courses of instruction, and have passed an examination of which part is always conducted by registered medical practitioners. Members of the society are pledged to work only under medical direction.

The house and library of the Royal Society of Medicine will be closed during the month of August for cleaning and repairs.

FIVE fellowships in neuro-psychiatry, each of the approximate value of £440 per annum, are available in the graduate school of medicine of the University of Pennsylvania, tenable for the period of three years from October 12th. The first year will be devoted to laboratory studies and instruction in clinics, the second to practical work, and the third to research. Further information may be obtained from the Dean of the Graduate School of Medicine, the University of Pennsylvania, Philadelphia.

On July 9th the President of the French Republic opened an Institute founded by Emile and Louise Deutsch de la Meurthe, which will provide furnished apartments at reduced prices to a large number of men and women students in the University of Paris.

An account of the proceedings of the National Conference of Mental Hospital Authorities, which was held on April 21st, and was reported in our issue of April 25th, 1925 (p. 807), has been published in a pamphlet entitled *The Nursing Service in Mental Hospitals*, it may be obtained from H.M. Stationery Office, price 9s.

AFTER forty-seven years unintermitted work Professor Charles Richet of Paris recently delivered his last lecture in the presence of the dean of the faculty of medicine and a large audience of professors and students.

THE American Red Cross has presented 10,000 dollars to the French Red Cross for the assistance of the wounded in Morocco.

The first international congress on malaria will be held at Rome from October 4th to 6th under the presidency of Professor Marchiafava. The subjects to be discussed are the alkaloids of quinine, the biology of the malarial parasites, the epidemiology and statistics of malaria, further information can be obtained from the general secretary, Professor Bastroni, Via XXIV Maggio 14, Rome.

A CONGRESS on infant welfare will be held at Geneva from August 25th to 28th. It will consist of three sections, the first concerned with hygiene and medicine under the presidency of Professor Clemens Paquet of Vienna, the second concerned with social and preventive work under the presidency of Georges Scle, professor of international law at Dijon, and the third section, under the presidency of the Marquis de Aberdeen, will consider education and propaganda work.

A RÖNTGEN society for South West Germany has recently been formed at Heidelberg, consisting of members from Baden, Württemberg, Baden, Hesse, Hesse Nassau, the Saar, Rhineland, and Westphalia. The first meeting of the society will be held at Heidelberg in the beginning of October under the presidency of Professor von Weizsäcker, Medical Superintendent of the Samariterhaus Heidelberg.

DR. LUGENIO MESONERO ROMANOS, director of the *Ida Medica* of Madrid, is organizing a salon in which Spanish medical men can exhibit their paintings, sculptures, and other works of art.

THE Ausha Hospital in Northern Tanganyika has received through Sir Milsom Rees a gift of £2,000.

THE annual meeting of the German Pediatric Society will be held at Carlsbad from September 20th to 23rd, when the following subjects will be discussed: (1) Orthopaedics and pediatrics, by Dr. Spitz of Vienna; (2) transfusion of blood in pediatrics, by Drs. Opitz of Berlin and Morawitz of Würzburg.

THE fee for the identity card which must be obtained by foreigners staying in France for a period exceeding two months has been fixed at 68 francs. It will be valid for two years. The fee is reduced to 10 francs for students and workers.

THE June issue of the *Wiener Archiv für innere Medizin* consists of a *Festschrift* in honour of Professor Jakob Wartenhorst, formerly known as von Jaksch, of the German Medical Faculty of Prague on the occasion of his seventieth birthday and his imminent retirement.

THE eighteenth international post-graduate course at Vienna will be held from September 14th to 27th, and be followed by a week of special clinical instruction. The course deals with therapeutics in all branches of medical practice. Medical practitioners wishing to attend should communicate in writing with the Secretary of the international course, Schlosselgasse 22, Vienna VIII, from whom a detailed syllabus may be obtained. The fee for the course is 600,000 kronen.

A COURSE in dermatology and venereology will be held at Strasbourg from September 12th to November 7th, under the direction of Professor Prunier. The fee is 200 francs, and application should be made to him (2, quai Saint Nicolas, Strasbourg). Arrangements are being made for the reception of foreign students, and pension accommodation will be available at about 30 francs a day.

AN Italian Psychoanalytic Society has been founded with the *Archivio Generale di Neurologia, Psichiatria e Psicoanalisi* as its organ. All communications should be addressed to Professor M. Levi Bianchini, Direttore del Manicomio Provinciale, Teramo, Abruzzi.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **British Medical Journal** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **British Medical Journal** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the **Journal**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **British Medical Journal** are **MUSLUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are

MEDICAL SECRETARY Mediscera Westcent London

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams: *Bacillus Dublin* telephone 4737 Dublin), and of the Scottish Office 6 Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh* telephone 4361 Central).

QUERIES AND ANSWERS

VEGETABLE TARS AND CANCER

Dr BRUCE C KELLY (Buckland Newton Dorset) asks us whether any carcinogenic properties have been proved to exist in vegetable tars—in for example, those from pines. Many people he continues, use these on the same patch of skin for many years.

From inquiries we have made it appears that no vegetable tar has so far been experimented with in this connexion, except the tar prepared from hain by a Japanese observer. It yielded positive evidence.

SOLIDS OF MILK

Mr. T. D. HARPIS (R.C.S. (Abercrombyth)) asks (1) whether genuine milk from a herd of cows has been known to yield as little as 8.07 of non fatty solids (2) whether the refractometer is reliable as a means of determining the absence or presence of water in milk.

SUBNORMAL TEMPERATURE

"P. X. D." asks for advice as to the treatment of an habitual subnormal temperature. Does this he asks, necessarily mean a subnormal basal metabolism and does it require treatment with thyroid extract? Is any pathological significance to be attached to it or is it to be regarded as a mere meaningless anomaly? The patient concerned has a temperature of 97.2° and is otherwise fairly fit.

INCOME TAX.

Succession to Practice. Ownership of Books.

"F. C. V. T." has succeeded to a practice as from April 1st. The inspector of taxes asks for accounts for the three years 1922-1923 and 1924. They can be prepared on the basis of gross bookings from the books left behind by his predecessor—who however retained the cash book—but is the predecessor's permission necessary before the books be used in that way?

Assuming that there is no written agreement on the point, we are of opinion that the ledger was handed over to be used by "F. C. V. T." for any proper purpose in connexion with the practice and that his predecessor could not object to accounts being prepared therefrom for income tax purposes, at the same time it might be an act of courtesy to give him the opportunity of stating his views. There are however two points to which we might refer: first that gross bookings are misleading unless the figures are modified by a reasonable deduction for bad and doubtful debts and as "F. C. V. T." does not hold the cash book the means of making a calculated claim is missing; second if the profits of the practice should fall short from some specific cause since or by reason of the succession, "F. C. V. T." will be entitled to throw the three years' average overhead and claim to subdivide the profit of the year of assessment. We suggest therefore, that the inspector might be approached with the

suggestion that having regard to the insufficiency of the data in "F. C. V. T.'s" hands and the likelihood that the change in proprietorship will cause a temporary falling off in the earnings he should agree to the making of an assessment on the same figure as before. It being understood that a detailed account will be forthcoming in due course for 1925-26, with a view to an adjustment of the assessment before payment of the second instalment of tax.

Request for Detailed Accounts

"A. P. L." has been asked by his local inspector of taxes to supply a copy of his accounts for each of the past three years. Can the inspector properly make this demand?

Assessments in respect of professional profits are made by commissioners (district or special) and not by the inspector and the latter has no statutory authority to demand accounts in support of a return. At the same time he is probably in a position to point out to the commissioners responsible for making the assessment that his request has not been met and the result might be the raising of an estimated assessment for the reduction of which our correspondent would have to produce the accounts. So that so long as the inspector's request is reasonable it may be advisable to comply with it. In this case "A. P. L." has the figures available, and we advise him to prepare a copy for the inspector and send it in, saying that he would call and discuss any point of doubt with him. The result will probably be satisfactory. To reduce the clerical labour involved the account might be drawn up showing the three years' figures separately in three columns in the one account. The employment of a firm of accountants is frequently resorted to by practitioners but hardly seems necessary having regard to the careful manner in which "A. P. L." appears to have prepared his calculations and statements.

Annual Payments from Gross Receipts

"W. C. H." has acquired a panel practice, covenanting to pay "for four years quarterly 20 per cent of all payments which he receives as a panel doctor" after deducting £175 from such receipts. Is he entitled to deduct income tax from such payments?

This is a question which materially affects the vendor of the practice and we have some hesitation in expressing a definite opinion without fuller knowledge of the course of negotiation and of the contentions based on the particular facts of the case which might be put forward on behalf of the vendor. It may be sufficient, however to explain the principle involved. In *Chadwick v. Pearl Life Assurance Company*, [1905] 2 K.B. 507, Walton, J., said: "It is obvious that there will be cases in which it will be very difficult to distinguish between an agreement to pay a debt by instalments and an agreement for a loan consideration to make certain annual payments for a fixed number of years. The distinction is a fine one and seems to depend on whether the agreement between the parties involves an obligation to pay a fixed gross sum. In my judgment the annual payments (in the case under consideration) were not paid as instalments of a debt, but were amounts payable and receivable as income." The trend of this judgment is in favour of the contention that tax can be deducted by "W. C. H." from the payments for which he is liable. It may be, however, that the fact that the capital value of a practice is usually computed by reference to the gross income would be held to constitute a distinguishing feature.

Cessation of Work

"B. G." gave up all professional work in January 1925 owing to ill health. What does he return (if anything) as his earnings for 1925-26?

He should return nil. His professional work had ceased before April 5th, 1925, and, assuming that he does not resume during 1925-26 he will have had no source of earnings for that year and will not be assessable for professional work. Any odd sums he may receive for past work will relate to earnings of years for which his liability has already been accounted for on the statutory basis of the three years' average.

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments in hospitals will be found at pages 32, 33, 35, 36 and 37 of our advertisement columns and advertisements as to partnerships, assistantships and locum tenencies at pages 34 and 35.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 48.

An Address ON EXPERIMENTAL POLYURIA

SIR I. SHARPPY-SCHAFER, Hon M.D., F.R.S.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF EDINBURGH

Since experimental polyuria depends upon injury or disease of the pituitary body, or, as some hold, of the nervous system in the immediate neighbourhood of the pituitary, it will be well first of all to draw attention to the main features of structure of the pituitary which might have a bearing on the subject.

ANATOMICAL CONSIDERATIONS

The pituitary lies at the base of the brain in the sella turcica and is connected with the third ventricle by a stalk, which is hollow as far as the gland, the hollow extending in some animals far into the interior. This hollow stalk is the infundibulum. Its wall is formed by a prolongation of the nervous tissue of the floor of the ventricle. This tissue expands into the posterior part of the gland, forming a solid mass of neuroglia—the pars nervosa or pars infundibularis. Nerve cells are absent. It is composed mainly of neuroglia with a few nerve fibres. Surrounding and enclosing the stalk is a cross-section of the stalk substance, which spreads from the stalk over the neighbouring part of the brain, especially over the tuber cinereum. This forms the pars tuberalis. Anterior to and higher than the pars tuberalis, the pituitary is formed of a mass of epithelium cells of granular appearance. This mass constitutes what is known as the pars anterior. It is the most vascular part of the gland, and when exposed in the living animal is conspicuous by its pronounced yellowish red colour. In most mammals there is a cleft in the middle of the gland which separates the organ into two lobes, a larger anterior and a smaller posterior. In the adult human subject the cleft is generally obliterated. In front of the cleft is the pars anterior, which forms the anterior lobe of the gland behind it is the pars nervosa, but this part is covered by an epithelium layer which is intimately adherent to it, termed the pars intermedia. The pars nervosa plus the pars intermedia together form the posterior lobe. The organ is easily separable into the two lobes by splitting it across in the line of the cleft. The cleft is the remains of the original tube which is formed in the early embryo from an outgrowth of the buccal ectoderm. The tube communicates at first with the buccal cavity, although the communication becomes obliterated later.

Pars Anterior

This composes by far the larger portion of the gland, and is formed of epithelium separated by connective tissue stroma. The epithelium is arranged in cord like or isolated masses of cells. These masses are usually solid, but sometimes the cells surround a vesicle filled with "colloid," which is no doubt secreted by the cells. Very numerous thin walled sinus-like blood vessels traverse this part of the gland. They lie in intimate relation to the cells, the secretion of which is probably pressed directly into them. The great vascularity of the pars anterior is very apparent in a photograph of an injected gland.

Pars Tuberalis

The larger portion of this forms an extension of the gland forward over the tuber cinereum. This portion corresponds with what was termed by Herring the "tongue like process." He described it as an extension of the pars intermedia but alike in structure and development it is distinct both from the pars intermedia and pars anterior. Its cells are basophil not oxyphil they are for the most part

arranged around colloid-containing vesicles somewhat like those of the thyroid. In vascularity the pars tuberalis closely resembles the pars anterior, so that in a photograph from an injected specimen the two parts are almost indistinguishable. Moreover, its capillaries have a sinusoid character like those of the pars anterior. This extensive vascularity renders it probable that it has an important function to fulfil. As we have seen, the pars tuberalis extends around the stalk of the pituitary in the form of a ring, which spreads over the adjacent part of the base of the brain, especially over the tuber cinereum.

Pars Intermedia

The pars intermedia lies immediately behind the intra-glandular cleft, covering the anterior surface of the pars nervosa, around which in many animals it sends a sheath-like prolongation for a variable distance. Here and there it extends into the substance of the pars nervosa. These extensions may become cut off from the rest and appear as islets of pars intermedia in the thickness of the pars nervosa.

The cells of the pars intermedia are smaller than those of the pars anterior. They resemble the cells of the pars tuberalis in being devoid of the coarse oxyphil and basophil granules which characterize those of the pars anterior. Here and there they may be seen surrounded by vesicles occupied by colloid. Occasionally this is considerable quantity and the vesicles are correspondingly large, on the other hand, it is sometimes absent. Besides such colloid as is contained within the vesicles the pars intermedia often exhibits globular masses of a similar substance of varying size not enclosed within vesicles (Herring's bodies). Some of these masses contain the remains of a nucleus, and have evidently been produced by a chemical transformation of the protoplasm of some of the epithelium cells. They are traceable into and through the pars nervosa, and can even be seen passing into the infundibulum of the third ventricle owing to its extension into the pars nervosa. It appears that they may undergo a further chemical transformation in the passage, for, according to Herring, extracts of pure pars intermedia and of pure pars nervosa show profound differences in their physiological effects.

The passage of colloid masses from the pars intermedia into and through the pars nervosa to be ultimately discharged into the third ventricle and thus into the cerebro-spinal fluid was discovered by Herring. He concluded that the substance of these masses represents the secretion of the pars intermedia, which is thus pressed into the ventricle. Herring's observations have been abundantly corroborated by subsequent workers who have used the same methods of fixation and staining. It is probable that the pars nervosa owes the physiological activity of its extracts to this material.

Confirmatory evidence that the active principles of the pituitary body can pass into the cerebro-spinal fluid has been furnished by various observers. Harvey Cushing and Goetsch found that the cerebro-spinal fluid when reduced in amount by evaporation will produce some of the characteristic effects of extracts of these extracts—that, namely, of producing extreme contraction of uterine muscle—was unknown at the time of their experiments. More recently this uterus-contracting or oxytocic principle in cerebro-spinal fluid Douglas Cow, working with Dixon at Cambridge was the first to show that duodenal extract if injected into the blood will produce after a certain interval unmistakable evidence, is tested with a certain cornu of the presence of the oxytocic principle in the cerebro-spinal fluid. More recently Dixon and Marshall of Cambridge have shown that ovarian extract is also a powerful stimulator for the pituitary, causing the oxytocic principle to be passed into the cerebro-spinal fluid. This only occurs in the absence of the corpus luteum from the ovary. Extracts which are made from an ovary during the greater part of pregnancy do not produce this effect,

* Address to the Inter State Post Graduate Assembly of America, Friday June 19th 1925

We have seen that the pars nervosa contains the colloid masses of Herring which are passed into it from the pars intermedia. There can be observed to make their escape into the extension of the third ventricle towards the pituitary, and, as Herring has shown, the greatly increased in number after thyroidectomy. Mott has made a similar observation in a case of myxoedema occurring in man.

Vascular Supply

With regard to the vascular supply of the pituitary, Goetsch has shown that in the dog it is supplied by a large number of arterioles derived from the circle of Willis and from a communicating branch uniting the internal carotids. The arterioles converge towards the infundibulum and are conveyed to the gland along its stalk. Most of the blood is distributed to the pars anterior. The venules of the blood are also very numerous, pass at first to the stalk and then diverge and form small veins radiating outwards to enter a venous circle roughly corresponding with the arterial circle. It is evident from this description that severance of the stalk would entail cutting off the main blood supply of the gland. There appears to be no true lymph vessels in the gland. Lymph which is formed within it must find its way through the space between the neuroglial fibres into the third ventricle or its extension.

Venous Supply

Very little is known of the venous supply of the pituitary. It is known that the venous supply of the infundibulum is made up of a similar system of veins occurring in man.

Very little is known about the nerve supply of the pituitary. Fibres have been described as passing along the stalk from sympathetic branches on the internal carotids. Such nerves are doubtless derived from the superior cervical ganglion. They are non-myelinated and are probably mainly distributed to the blood vessels. But myelinated nerve fibres have also been seen ending in ramifications amongst the cells of the pars anterior. Apparently there are no nerve cells in the pars nervosa.

PHYSIOLOGY

It is not necessary to describe all the physiological effects which are produced by extracts of the posterior lobe of the pituitary body but in connexion with experimental physiology it is important that certain facts should be pointed out. The first is that extracts of the posterior lobe of the pituitary when injected into the vascular system cause a great rise of blood pressure with contraction of arterioles and increased force of the heart beats. Sometimes the pressor effect is preceded by a fall of blood pressure and in a second dose is administered there is always a fall and no subsequent rise. This appears to be due to the fact that there are two antagonistic principles in such extracts, one causing elevation of blood pressure and the other depression. The principle which causes fall of blood pressure is if not identical with at any rate closely allied to histamine. This is shown not only by the effect on the ordinary pressure but also by that which is produced upon the extract of posterior lobe of pituitary body is apt to cause along with the raising of the aortic pressure, a lowering of pulmonary pressure. But we have found that if the histamine-like substance is first completely extracted by absolute alcohol only a pressor effect is obtained, in both aortic and pulmonary systems. The rise of blood pressure is due to general contraction of arteries, but those of the kidney, in place of being contracted are relaxed by the extract.

[T 1 116
L J T 42]

Diuretic Action

For our present subject this exception is of great importance since the dilatation is correlated with an increase of secretion of urine, often very marked. This effect may be preceded by a slight contraction and the increase of urine by a temporary diminution. The increased secretion might be explained by the increased flow of blood through the kidney vessels due to the circumstances that they undergo dilatation while the other systemic arteries are contracting so that the blood pressure in the glomeruli is raised but that it is to a certain extent caused by a specific effect of one of the pituitary principles, and is not merely a mechanical result of increased blood pressure, is probably obvious from the fact that it may occur in the absence of any rise in blood pressure. Moreover, if there is at first a rise in blood pressure the increased rate of flow of urine is maintained even after the blood pressure has come back to its original level. And the effect of a second dose of the extract is again to produce an increase in the flow of urine, although the blood pressure no longer rises but falls, and although the kidney volume may now be unaffected. This would seem to indicate that the active principle affects not only the blood vessels of the kidneys but also its secretory cells, which it renders more permeable and the effect must be looked upon as caused by a chemical action on the renal cells similar to that of secretion on the cells of the pancreas. In this respect the action of the diuretic principle is comparable to that of those drugs which act as specific diuretics, the diuretic action of the pituitary is not antagonized by anæsthetics by merely increasing the general blood pressure. This may be taken as a sign that it does not act through nerves or nerve endings but directly upon the renal cells. In this respect also it resembles the action of the ordinary extracts of the posterior pituitary body, which we are now considering.

Indiurmic Action

Besides the diuretic action of extracts of posterior lobe, these are found in certain circumstances to bring about exactly the opposite condition. When intravenous injections of pituitary extract are made, there is, as we have seen at once, a very temporary diminution of flow of urine followed by a prolonged increase. On the other hand, with subcutaneous or intramuscular injection, especially if polyuria is already present, a great diminution in the secretion is produced. The anti-diuretic action was first noticed in clinical cases of diabetes insipidus, in which it has a remarkable, indeed specific, action in controlling the excretion of water by the kidneys and bringing it down to a normal level. To keep it at that the injections require to be repeated from time to time. In normal individuals the effect is less striking.

Most experiments on the anti-diuretic action of pituitary extracts have been made on water diuresis—that is, the polyuria which is produced by drinking large quantities of water. If pituitary extract is administered previously to taking large quantities of water, a considerable delay of the water diuresis occurs, and during this there are nervous symptoms, due doubtless to the accumulation of water in the system, which are sometimes of a serious character. Molitor and Pick find that the toxic effects which may be caused by pituitary when a large excess of water is administered can be at once removed by the administration of mercuric iodine, which probably acts by removing the excess of water from the tissues in which it has been stored and causing its rapid excretion by the kidneys. They conclude that the anti-diuretic effect has nothing to do with the renal vessels or with the renal cells but is an effect

on the tissues, perhaps also on the capillaries, and that one of the main functions of the pituitary is to determine the amount of water the tissues can hold.

Polymuria as a Result of Pituitary Lesions

A very common effect of experimental injury of the pituitary is polymuria. Considering that extracts of the posterior lobe of the pituitary produce diuresis when injected into the blood, it seems possible that injury of the lobe without removal may produce irritation either of the pars intermedia or of the pars tuberalis, and thus cause the outpouring of an increased secretion from these parts of the gland. The polymuria which is often found to accompany fractures of the base of the skull may be due to a concomitant injury of the pituitary. Meticulous manipulation of the posterior lobe without causing any obvious lesion will produce polymuria, but exposure of the gland by literal operation without manipulation or injury has no such effect. In one experiment on a dog of injury of the posterior lobe by a touch with the electric cautery I found the amount of urine secreted to rise from 40 c.c. a day to 220 c.c. For nineteen days it showed an average of 119 c.c. In another experiment the amount of urine rose from 110 c.c., the average for the preceding eleven normal days, to 182 c.c. for the eleven days immediately subsequent to the operation, and on some of these days it reached much more than this, attaining as much as 266 c.c. Many others have recorded cases of temporary or permanent polymuria produced by an injury to the pituitary body or to its stalk. It is true that in some of these there were injuries to the adjacent part of the brain, but this was not the case with all of them. Cushing obtained diuresis by stimulation of the cervical sympathetic or of its superior ganglion, and, according to him and his fellow workers, puncture of the pituitary may give as definite results regarding glycosuria and polymuria as Bernard's puncture of the fourth ventricle.

Most of the experiments the results of which in causing polymuria, with or without glycosuria, have been recorded have taken no account of the pars tuberalis. This part cannot easily be studied separately by reason of the fact that it is intimately united with the base of the brain, over which it spreads for some little distance. It may be that this portion of the pituitary is responsible for the polymuria which is frequently associated with injury of the gland, and either injury to the pars tuberalis or interference with the blood supply of the gland may be accountable for the results which have been recorded by Camus and Roussy. These observers have obtained in the dog, cat, and rabbit, but not with the same facility in all, polymuria and glycosuria from injuries by puncture or cautery to the floor of the third ventricle (tuber cinereum) in the immediate vicinity of the pituitary—apparently, as they state, without injury to the gland itself. They consider that in all cases the polymuria is due to the brain lesion and not to any effect on or through the pituitary, which, even, they state, be removed previously without affecting the results. But it may be stated that it is not possible to remove the pars tuberalis without injuring the base of the brain. Camus and Roussy even ascribe the dystrophia adiposo-genitalis and all the other effects which have been put down to lesions of the pituitary to injuries of the tuber cinereum.

Similar results have been recorded by Bailey and Bremner as being produced in the dog by a puncture by a probe in the base of the brain in the neighbourhood of the pituitary, without in any way directly injuring the gland, the integrity of which was verified histologically (although the pars tuberalis is not mentioned). Polymuria resulted from even the smallest puncture. It is significant that it began, not immediately, but within the first two days and lasted six to eight days or longer. When it was persistent the symptoms known as diabetes hypophyseoparva, general atrophy, and adiposity were also manifested, all suggestive of pituitary insufficiency. The persistent polymuria when it occurred had all the characteristics of diabetes insipidus in man, such as concentration of urine when intake of water was restricted, excessive polymuria when chlorides were injected, diminution of urine when posterior lobe extract

was injected, etc. According to these authors polymuria is never produced by lesions outside the pars infundibular region, but nevertheless in their opinion it is not caused by the agency of the pituitary directly or indirectly.

Although there can be no question as to the facts recorded by the above mentioned authors, it is difficult in view of the numerous observations on the effects of lesion confined to the gland and of the administration of extracts of the gland, to believe that most, if not all, of the symptoms described have not been produced through the agency of the pituitary. It is difficult to believe that a minute lesion of the floor of the third ventricle, very different in structure and nerve connexions from the floor of the fourth ventricle (in fact of simpler structure and with fewer nerve connexions than any other part of the brain and having no trace of glandular structure except that which is derived from the subjacent pituitary body) should produce *per se* such far-reaching results as these described, and hitherto attributed to disturbances in the activity of the pituitary itself. It seems a more rational conclusion that the perihypophyseal lesions effected by Camus and Roussy and by Bailey and Bremner produce their effects by disturbing the normal functions of the gland, either through its vascular supply or perhaps through hitherto unrecognized nervous connexions, or by interfering with the passage of products of the secretion of the pars intermedia into the ventricle, rather than by direct nervous action.

Most of the discussion has turned on the question of the production of polymuria from lesions of the base of the brain in the perihypophyseal region. The fact that polymuria is produced by such lesions even when the kidneys are completely denervated is a clear indication that the cause of the polymuria is humoral rather than nervous. This and the fact that it does not make its appearance until the next day or the day after are suggestive of an indirect action through the pituitary rather than of a direct effect from the brain lesion, which, as in the case of Bernard's puncture of the fourth ventricle, would produce its effects immediately.

THE PRESENCE POST MORTEM OF NITRIC-OXIDE-HAEMOGLOBIN

ITS CLINICAL AND MEDICO-LEGAL SIGNIFICANCE

BY

H. A. L. BANHAM, L.R.C.P., J. S. HALDANE, M.D.,
F.R.S., AND THOMAS SAVAGE, M.B.

THE case on which the present paper is mainly founded was one in which there is every reason for believing that *post mortem* appearances which simulated very closely those of carbon monoxide poisoning were due to the formation of nitric oxide-haemoglobin after death.

A man employed at a colliery in stoking the boiler furnaces became ill on his way home after a full day's work. He became faint and unable to stand. Even after a rest he was unable to walk more than a few yards, and he was brought home in a car. His skin was very cold and he was very feeble. During the night he was bringing up blood-stained sputum. He was seen next day by his doctor who found that his pulse was feeble, his breathing heavy, his temperature normal, and that he was complaining of a feeling of compression in the chest. Carbon monoxide poisoning was suspected and he was kept in bed, but the symptoms continued including the blood-stained sputum. On the ninth day after his illness began he was getting worse and was sent in a taxi to the Beckett Hospital, Barnsley, with a view to treatment by transfusion of blood. When seen on arrival by one of us (T.S.) he was very cyanosed and evidently moribund, and he died within ten minutes.

A *post mortem* examination (by T.S.) was made within a few hours. The only signs pointing to the cause of death were as follows. The lungs contained much frothy blood-stained liquid and showed patches of pneumonia though they floated in water. There was also a good deal of fluid in the pleural and pericardial cavities and the heart muscle showed signs of fatty degeneration. The whole of the blood, in whatever part of the body, including heart, spleen, kidneys, muscles and lungs, had a red or pink colour entirely different from the dark colour normally seen at first on cutting into these organs in *post mortem* examinations.

This appearance was thus identical with that in a case where death from carbon monoxide poisoning had occurred while the victim was breathing the poisonous air or directly afterwards. On dilution with water the blood gave a pink

precipitate with tannic acid solution, and on addition of caustic soda to the diluted blood the red colour remained. These are well known tests for the presence of carbon monoxide. As no spectroscopic test was applicable but there is every reason to believe that if it had been applied it would have confirmed the apparent presence of carbon monoxide. No existing textbook gives correctly the distinguishing test for nitric oxide haemoglobin and this substance has never hitherto been recognized *post mortem* in man, so that the possibility of its presence was not suspected at the time.

In view of the difficulty in assuming that carbon monoxide in large amount could have entered the living body for many days, it was suggested at the request that the poisoning had occurred in the conveyance which brought the patient to hospital or at his home. It is known that during the war a number of cases of carbon monoxide poisoning occurred in unbalanced cars through exhaust fumes being carefully sucked into the cars. These possibilities were carefully sifted by the coroner and definitely excluded. He thus found himself forced to conclude that not only was carbon monoxide the cause of death but the gas had been absorbed at the colliery nine days before death.

To the management and advisers of the colliery company (who had consulted the Birmingham University Mining Research Laboratory, of which one of us is director) it seemed, however, almost impossible that the carbon monoxide poisoning could have occurred there. The place where the man was working was in a current of fresh air passing into the furnaces. A man who was working beside him was not affected, and tests made afterwards by a very delicate method showed no trace of carbon monoxide in the air. Had the man absorbed any considerable amount of carbon monoxide during his work he would certainly have been affected at the time and not merely afterwards. The onset of his symptoms suggested something of the nature of a rigor, and then continued afterwards with the stunted sputum and other respiratory symptoms suggested some form of pneumonia. In my case the *post mortem* appearances were such as are only present when the blood is so highly saturated with carbon monoxide as to produce loss of consciousness. All experimental evidence and evidence from actual cases of carbon monoxide poisoning in man shows that carbon monoxide is expelled so rapidly when present in the blood that within a very few hours the presence of the gas in the blood cannot be detected. The mitter came into court on a claim against the company for compensation, and after evidence was heard the claim was dismissed.

The only cause which is known to be capable of producing the red colour of the blood and the other reactions which were found is the presence of nitric oxide haemoglobin. This compound, discovered by Hermann in 1865, is formed when nitric oxide is brought into contact with reduced blood. The colour of the blood changes at once from dark purple to the bright scarlet shown also by blood saturated with oxygen or carbon monoxide. A double banded spectrum, similar to that of oxyhaemoglobin but broader, is formed. However, much less sharply defined than those of oxyhaemoglobin, and somewhat less than those of CO haemoglobin. The NO haemoglobin band in the yellow extends, also, to a slight distance on the red side of the D line. On great dilution with water oxyhaemoglobin appears yellow in daylight, while CO haemoglobin and most delicate means of detecting the presence of carbon monoxide in blood. NO haemoglobin gives a tint which is pinker than that of oxyhaemoglobin, but not nearly so pink as that of CO haemoglobin. The solution of NO haemoglobin can be distinguished at once by boiling, since it gives a pink coagulum while oxyhaemoglobin and CO haemoglobin being stable in the boiling water and of a red colour. In other respects, NO haemoglobin gives similar reactions, including spectroscopic ones. It is only formed when nitric oxide comes into contact with reduced haemoglobin, NO haemoglobin would be only a chemical curiosity. In actual fact, however,

NO haemoglobin and its products are very familiar. It was shown by one of us that the red colour of raw salted meat is due to the presence of NO haemoglobin, while the corresponding pink colour of cooked salt meat is due to NO haemochromogen. The nitric acid in salting the meat becomes reduced in the meat to nitrite, and in presence of the reduced haemoglobin, which is also there, the nitrite becomes further reduced and the resulting NO combines with the reduced haemoglobin to form NO haemoglobin. It had already been shown by Haldane, Milgall, and Muriogordito that in animals which have been killed after receiving a dose of nitrite the blood becomes bright red after death and the possibility of this being the formation of NO haemoglobin was pointed out at the time.

When nitrite is given to a living animal methaemoglobin is formed. Not only, however, is this the case, but a certain amount of NO haemoglobin is also formed, as was shown by the above named authors. The colour of the blood solution treated with nitrite is therefore reddish brown in contrast to the dull brown of pure methaemoglobin. The contrast in both colour and spectroscopic appearance becomes much more evident on making the solution faintly acid by shaking it with expired air. On reducing the methaemoglobin with ammonium sulphide the whole of the haemoglobin pieces very gradually into NO haemoglobin or on boiling the whole passes rapidly into methaemoglobin so that the coagulum is pink. Nitrite poisons an animal by depriving the haemoglobin of its oxygen carrying power just as CO does, but the animal has a very marked appearance contrasting with the red colour in poisoning by CO. The cyanosis is not due to the presence of reduced haemoglobin, but to that of methaemoglobin.

In a quite recent paper Auer and Mirsky draw the conclusion that NO haemoglobin is a compound of NO with methaemoglobin. There appears to be no real grounds for this inference. When NO is added to a solution of oxyhaemoglobin or of CO haemoglobin when free oxygen is also present the first effect is that the NO combines with the available oxygen and turns nitrite in the solution. This in its turn produces methaemoglobin and turns the liquid brown. Only on further addition of NO is the methaemoglobin reduced and then converted into NO haemoglobin but this does not show that NO haemoglobin (which is formed directly if no oxygen was present) is a compound of methaemoglobin. Both the colour and the spectrum of NO haemoglobin indicate that it is a compound analogous to oxyhaemoglobin and CO haemoglobin. It will now be evident that provided an infective micro-organism produces nitrite within the body we can easily account for the presence of NO haemoglobin *post mortem*. The presence as well as the immense importance of nitrite from organisms in the soil has been a familiar fact for long, but hitherto no knowledge has accumulated with regard to nitriding organisms. The present case, if a nitriding organism was accumulated with might therefore be regarded as quite exceptional. That it is by no means exceptional is however indicated by observations made by one of us (H. A. J. B.) while he was in command of the medical section at the military hospital at Cannoek Chase during the great epidemic of influenza in 1918. During this epidemic there were many deaths from influenza pneumonia, and it was noticed again and again that the bodies had a red colour, and the blood when first exposed had a red or cherry red colour, just as in CO poisoning, though actual CO poisoning could not have occurred. He made a special military report on this remarkable fact, although at the time the possibility of NO haemoglobin being formed had not been considered. He found that at least two other officers serving in the R. A. M. C. at the time had made similar observations— one being Dr. David Smith now of Glasgow, who was a colleague at the Cannoek Chase Hospital, and the other Professor Connell of Sheffield University. The case it is he was watching the case on behalf of these observations, and him to doubt whether the red colour found was due to carbon monoxide.

We think that there can be little doubt that the colour

found was actually due to NO haemoglobin, and that the pathogenic organism which was present in this case, and probably in many other cases accompanied by dangerous bronchopneumonia, is a nitrifying organism. In cases of infective bronchopneumonia the lips have often a bluish or lavender colour and it seems to be impossible to restore their normal colour by adding oxygen to the inspired air, though in other types of cyanosis accompanying lung affections—for instance, in lobar pneumonia or phosgene poisoning—the oxygen is effective. This may be due to the fact that in the former case the pulmonary circulation continues through the blocked areas, so that the oxygen cannot reach the present blood while in lobar pneumonia the pulmonary circulation through the consolidated lung ceases. If, however, a nitrifying organism producing nitrites is present, it seems probable that the cyanosis or part of it may be due to the presence of methaemoglobin in the arterial blood, as in poisoning by nitrite. This might have an important bearing on both prognosis and treatment, but until further observations are available the matter need hardly be discussed further. Very marked cyanosis was observed in the present case. This shows that the red colour was produced

after death. In all probability the cyanosis was largely due to methaemoglobin.

Methaemoglobin and other coloured products of decomposition of haemoglobin can be detected most easily by diluting a drop of the suspected blood till the colour becomes yellow, diluting to an equal colour strength a drop of normal blood and then saturating both solutions with coal gas or carbon monoxide. The presence of abnormal pigment is indicated by the fact that the corresponding solution is less pink.

It is evident that from a medico-legal standpoint the possible presence of NO haemoglobin must now always be considered in cases of suspected CO poisoning. The distinction can be made with great ease by boiling a watery solution of the blood. If the red colour and other corresponding chemical reactions or spectroscopic appearances are due to NO haemoglobin the coagulum will be pink. No other simple test at present known appears to be reliable for distinguishing CO haemoglobin from NO haemoglobin.

DISCUSSION ON FILTER-PASSING VIRUSES AND CANCER

[Dr Gye had prepared the following paper as an introduction to the discussion, it was not read, as he devoted his time to giving a brief account of his researches into the virus of malignant new growths. The paper is printed here owing to its intrinsic interest and its bearing on the general question of filter-passing viruses.]

I

WILLIAM DWIGHT GYE, M D Edin.,

Assistant, Department of Experimental Pathology, National Institute for Medical Research, Hampstead

I HAVE no wish to take up time in a general review of the subject of "filterable viruses", this has been done so often in the larger textbooks of bacteriology and in special monographs as to make the repetition of the history of the subject wearisome. We are all compelled, clinician and bacteriologist alike, to take an active interest in the subject because of the importance of the diseases which are with reason attributed to the activity of the very small, invisible microbes. It is my wish rather to discuss the subject from the standpoint of the working bacteriologist, and especially to lay before you those parts of my experience which seem to me to have a general value.

Before embarking upon this, I should like to say a few words upon the term "filterable viruses," and to offer some comments upon the various attempts which have been made to classify the viruses on the basis of their pathological action.

The term "filterable virus" implies that the common property of the ultramicroscopic organisms is filterability through a candle already proved to be impervious to ordinary small microbes. When the vesicular fluid of a vesicle in foot-and-mouth disease is taken and largely diluted—for example, 0.2 ccm with 30 to 50 ccm of saline—and the mixture is filtered through a candle, the infective agent passes through apparently without loss. This fact, discovered by Loeffler and Frosch twenty-seven years ago was the first definite "filterable" virus, it still influences the bacteriologist to such an extent that filterability is regarded as the final test of an invisible virus

The contents of a herpetic vesicle may be diluted with saline, filtered, and the filtrate is infective, as is determined by its power to cause pathological changes in the brain of the rabbit. If, however, infective brain tissue be taken from a rabbit ill with, or dead of, herpetic encephalitis, and the tissue be ground thoroughly with sand, diluted with saline, filtered through sand (or spun) to remove coarse particles, and then passed through a fine candle, the final filtrate is non-infective. Here we can only conclude that the virus has become so firmly attached to brain tissue that it is not possible to separate them by ordinary mechanical processes. Filtration, in other words, breaks down. Again, calf lymph which undoubtedly contains the virus of vaccinia may be filtered, but the filtrate does not contain the virus. It is possible that the virus may be attached to the contaminating cocci usually present or it may be that it has the property of being adsorbed on to the surface of the filter. These, of course, are mere speculations, but the fact is, in spite of Borrel's reported success, that the virus in calf lymph does not pass a fine filter.

My own experience in the filtration of a virus has been particularly with the Rous chicken sarcoma. Here, if one takes tumour tissue and grinds it thoroughly with sand and then dilutes with an adequate quantity of saline or Ringer's fluid removes the coarse particles by preliminary filtration through sand and paper pulp, and then passes the fluid through a candle—for example, a Chamberland L2 or a Mandrel—the cell-free filtrate is found to be sterile in the ordinary sense but will cause the formation of a sarcoma, identical in structure and biological properties with the tumour from which the filtrate was obtained, when injected in a dose of 1/2 to 1 ccm in a chicken. If the tumour emulsion be insufficiently diluted, or if distilled water be employed instead of saline, the filtration is much more difficult and it is seldom that an infective filtrate is obtained. The reason for this is as follows. By using a small volume of saline or by using distilled water as a diluent, one obtains a viscous solution of nuclei and nucleo-protein which will not pass the filter readily. The hydrogen ion concentration of the liquid also affects the rate of filtration, within limits, not yet

tubes of medium containing fresh tissue always causes, sometimes rapidly, the formation of colloidal protein complexes, and it is possible that the virus is spun down on these. In other words I do not think it is a clean proof that the virus is particulate. The influence which the acidity has upon the result can be indicated by another experiment. It has already been mentioned that alkaline candle filtrates are unsuitable for spinning experiments. If, however, the pH of such a filtrate be altered by the addition of K_2HPO_4 , the acidity being adjusted to about 5.0, then such an acidified filtrate when spun will show an obvious difference in the infectivity of the uppermost and lowest layers. This experiment I accept as a demonstration of the coprecipitation character of the virus. If the centrifuge tube be lined with a thin layer of nutrient agar filled with an acid culture, and then spun, the spread may be reduced to about 6,000 and the time to forty minutes in order to lower the infectivity of the fluid. It is relatively easy in this way to make a fluid, which in a dose of 1/2 c.c. will cause a tumour, ineffective in a dose of 1.5 c.c. What the agar does beyond providing a sticky surface for particles to adhere to I do not know.

(2) Almost every dye has been tested in attempts to stain filterable viruses. Cameron's stain has found most favour though polychrome methylene blue has had a good deal of support especially from those who have studied influenza. I have tried these stains and many others in the course of my work on the Rous chicken sarcoma, without any success. The physicists tell us that an organism smaller than 0.2 μ cannot be resolved under direct illumination by the best lenses available. This may be so, but the hope which sustains us in attempting to examine stained preparations of a virus is that by the prolonged application of stains we may selectively "paint" the virus so that it becomes larger and visible. The hope, however, so far as the sarcoma virus is concerned, is illusory. The staining, to begin with, is not selective, the particles which are formed by the disintegration of tissue are stained also and it is impossible to distinguish them from virus. Moreover, colloidal particles apparently form on the slide in drying films and they stain pink with Giemsa's fluid. This can be illustrated by the following experiment.

A culture of the sarcoma virus was taken and a thin film made on a clean slide. A chicken was then inoculated. The culture was then spun in an agar lined tube at 8,000 for forty minutes. A second film was now made from the surface of the spun fluid and a second chicken was inoculated with 1 c.c. of the uppermost layer. The first chicken developed a tumour which was fatal in twenty days no tumour developed in the second chicken. It may therefore be presumed that the culture contained virus which was deposited by spinning. But the two films, the one taken before spinning and the second after dried in the same desiccator fixed together and stained together with Giemsa's stain, both showed pink particles at about the limit of resolution.

For a long time before this experiment was done I had believed such particles to be the stained virus. This experiment showed clearly that I had been in error. Possibly others have been deceived in the same way.

(3) The only value which the microscope has had in this research has been in revealing the presence of contaminating microbes. Contaminations have been interpreted differently, however, by other authors, to some, especially in the field of cancer research, they represent an interesting phenomenon. The filterable virus is regarded as mere, a phase in the life history of an organism, the contaminant constituting a second phase. Taking this view and disregarding classical doctrine of the fixity of form of bacteria—on at least straining beyond justification the fact that variations in size and form occur—such authors are not deterred from lumping together as one organism a mixture of virus cocci and bacilli. The view seems to me to be fantastic. My experience however is confined to two viruses—that of pleuropneumonia and the chicken sarcoma virus. The first is easily cultivated on serum agar or in serum broth and never in my experience shows any extraordinary variation in form or size. It is an organism on the border line of visibility. It may be stained and examined in the usual way though of course, the technical difficulties are greater than with ordinary cocci. Examination of stained films reveals a coccoid form which is constant in the morphology of

the organism is, of course, completely obscured by staining, but it is certain that larger forms, coccoid or bacillary, never appear in the cultures. The second virus is, as I have already pointed out, too small for direct microscopic observation, but cultures which become contaminated with recognizable microbes are ineffective in attempts to produce tumours. It is very probable that, with increasing knowledge of the ultramicroscopic organisms, we shall find that the doctrine of fixity of form holds here as well as with ordinary microbes.

(4) It has already been pointed out that each virus must be considered by itself. The organism of pleuropneumonia grows very readily on artificial media, it is apparently the only one which does so. It may be remarked that when the organism was first grown recourse was had to the method of cultivation in a collagen sac placed in the peritoneal cavity of a rabbit. Now that the virus is better known and more easily recognized, this procedure appears to be unnecessary. It is quite possible that the organism had often been grown, but not recognized because of the small size of the colonies before the first admitted cultivation in a collagen sac. The virus of the Rous chicken sarcoma may be grown in Huxley's broth to which is added 0.2 per cent potassium chloride, 1 c.c. of sterile rabbit serum to each 5 c.c. of broth, and a fragment of chicken embryo. The only proof that the virus has grown is the production of a tumour following inoculation into a chicken. It is not possible to judge growth by the appearance of cloudiness in the medium, this, indeed, is so often caused by the small growth of a contamination that it is advisable to discard such cultures. The production of cloudiness in Noguchi tubes has been put forward as a proof of culture, I have found that, so far as chicken sarcoma virus is concerned this is entirely erroneous.

(5) I have put this question forward because I wish particularly to stress one aspect of the search for the invisible viruses, and that is that the animal test is the final proof of the presence of the organism in an inoculum. The uselessness of the ordinary microscope is very disconcerting, as everybody who has worked at a filterable virus will testify. It certainly teaches us how much we owe to the microscope in our ordinary work. But here, in searching for the invisible organisms, we fall back in a very special way upon animal experimentation. It is because of this, and because ordinary laboratory animals are not susceptible, or only slightly so to human filterable diseases such as measles and influenza, that such small progress has been made. We shall be compelled to work at animal diseases if we wish to discover a method of handling and identifying the very small microbes. This, however, will involve large expenses and is open only to those who have ample funds behind them.

At the unanimous desire of the meeting Dr Gye did not read the above paper, but gave an account of his recent researches into the etiology of cancer. He began by pointing out that hitherto they had been satisfied with the general conception that all that was necessary in order to originate disease was that host and parasite should be brought together. Although this held for many contagious diseases, laboratory research had shown that the conception broke down when applied, for instance, to certain diseases due to anaerobic bacteria. Thus tetanus bacilli washed free from toxin were harmless for laboratory animals but a fatal disease ensued if sufficient toxin was also present. Although they had no definite knowledge with regard to other bacterial diseases there was much to suggest that a similar kind of force operated with them. Thus during the war, in some outbreaks of cerebro-spinal meningitis 50 per cent of the population were found to be carriers of the germ without contracting the disease. Similarly about 10 per cent of the population of this country harboured the cysts of amoebic dysentery, yet no great epidemic occurred. Clearly the meeting of host and parasite often failed to be marked by disease. Turning to cancer Dr Gye dealt first with the question of specificity. All species of animals suffered from cancer but until recently a tumour arising in one animal could only be transmitted to another animal of the same species, and this only by the

injection of living cells. This specificity and faithful reproduction of the parent tumour were often quoted by pathologists as evidence against the germ theory of cancer. But there remained one exception—namely, the chicken sarcoma discovered by Peyton Rous in 1911, which could be passed from one bird to another of the same breed by the injection of a cell free filtrate of the sarcoma. Subsequently two other tumours were discovered which could be handled in the same way. Each of the three filtrates from these tumours gave rise to a different variety of sarcoma imitating always the original tumour from which the filtrate was derived. Thus, the first was an embryonic type of sarcoma the second an osteochondrosarcoma, and the third a spindle celled sarcoma. Each of these could be ground up and diluted in saline and filtered in each case the filtrate reproducing in injected animals a like type of malignant growth. It seemed that each type of tumour must be caused by a specific type of virus and the opposite of the germ theory of cancer were quick to point out that a theory that necessitated a belief in a separate type of virus for each separate type of growth imposed considerable strain on scientific credulity.

Dr. Gye's explanation of the specificity of tumours has already been published, and he referred only briefly to some of his experiments which had led him to the conclusion that two agencies were necessary for the successful transmission of tumours—namely, a living virus and a specific substance derived from the tumour tissue. He described how, by rapid and prolonged centrifuging, he had divided up the filtrate from a chicken sarcoma into two elements—the washed deposit and the non-particulate supernatant fluid. Each of these alone was incapable of giving rise to malignant growth, but when both were injected sarcoma followed. He recounted how he had succeeded in producing tumours in mammals also with a cell free filtrate, thereby proving that mammalian tumours did not differ essentially from the filterable and infective tumours described by Rous.

II

Mr J E BURROUGHS, F.R.S. followed with an account of the microscopic examination of ultramicroscopic viruses. He defined the limitations of existing microscopes and described apparatus he had constructed which enabled him to photograph by means of ultra-violet light objects less than a fifth of a micron in diameter.

III

M H GORDON, CMG, MD, F.R.S., Consulting Bacteriologist St Bartholomew's Hospital

AFTER offering congratulations to Dr Gye on his success in cultivating a filter-passing virus *in vitro* and the brilliant application that he had made of it, and to Mr Burroughs on his wonderful development of the microscope for the present purpose, Dr Gordon remarked that his own work on another group of these viruses was complementary to theirs because he had employed neither culture *in vitro* nor the microscope.

Three years ago he had the honour of introducing a discussion in that Section on the subject of the etiology of influenza, when evidence was adduced that this disease was due to a pathogenic agent belonging to the filter passing group. In attempting to define further the characters of the minute anaerobic organism recovered from influenza patients he was baffled—partly by the irregular supply of material, partly by lack of knowledge of how to handle such organisms, but chiefly by the difficulty in deciding whether an animal that became ill after infection with this organism had true influenza or not. Similarly, there was no means of determining whether the animals that escaped owed their immunity to a previous attack naturally acquired.

It was determined, therefore, to drop influenza for the time being and to concentrate on a filter-passing virus that would produce an unmistakable specific lesion in a laboratory animal in the hope that information thus obtained would prove useful hereafter when handling influenza or other more difficult viruses.

The indicator selected was vaccinia, a virus which could always be obtained produced a perfectly typical lesion on the skin of the rabbit and had the great advantage that multiple inoculations could be made at the same time. Since then he had spent three years in an attempt to define the characters of vaccinia virus, a work latterly having been included in a report to the Medical Research Council, which was now in the press. He could not possibly describe the whole of this investigation in the time allotted, and must refer only to some of the more important results.

As regards the filterability of vaccinia virus Dr Gye had reminded that in ordinary circumstances this virus failed to pass the filter. Now as regards this point a great deal of work had been done. The positive evidence was as follows: Bath Raulinger and Nouri and Rouget had shown that by taking sufficient of the filtrate the presence of the virus in it could be proved. Nouri also had shown that if the supernatant in the cold store before filtering, the virus could succeed in passing it through the Berkefeld filter after liberating the virus from the cells by trypsinization. Finally Levaditi and Nicolin showed that vaccinia virus is readily adsorbed by substances analogous to those that compose the Berkefeld and other filters, and further that when filtered through a cellophane membrane the pores of which were exceedingly fine vaccinia virus passed through more readily than did the viruses of rabies, herpes, and encephalitis. In face of this wealth of positive evidence there could be no reasonable doubt that vaccinia belonged to the filterable viruses.

In the present investigation the ordinary microscope was only used to exclude contamination from bacteria. No attempt had been made to cultivate the virus *in vitro*. Animal experiment and ordinary immunological and serological methods alone were employed. As vaccinia virus produced a typical and specific lesion on the shaved and scarified skin of the rabbit, this had been made use of to study some of the chief characters of the virus. The work had been as far as possible quantitative throughout. In submitting the virus containing material to a known degree of dilution before inoculation the amount of active virus present had been accurately determined and the result expressed in minimal vaccination doses, or MVD. Similarly, the degree of immunity obtained by various prophylactic measures had been measured by applying falling doses of virus to the rabbit's skin and thus ascertaining the number of MVD to which the animal was immune. When preparing antivaccinia serum pulp was made from the vaccinia lesions on the rabbit's skin, and the suspension of virus thus obtained free of foreign protein was injected into further rabbits. The antiserum prepared by this method only contained antibodies to the virus.

The remainder of the communication was illustrated by tables thrown on the screen by lantern slides. The virus contained by seven different specimens of calf lymph in MVD to 5000 MVD per cubic centimetre, and the same brands tested two years later gave a result similar to that given before. The effect of various disinfectants on the vaccinia virus was next shown and attention drawn to the very strong "virucidal" effect of potassium permanganate which considerably exceeded even mercury. A pronounced virucidal capacity of permanganate pointed to a fundamental weakness of the virus to oxidation, a point emphasized by Repin of the Pasteur Institute in 1909 in course of a study of the biology of vaccinia virus. The effect of heat upon the virus was next determined, and exposure to 55°C for thirty minutes either destroyed the virus or almost entirely destroyed it, a comparison was made of the prophylactic value of the raw virus with the same virus heated in this way. It was found that by raising the dose of this heated virus, a point was reached at which the immunity produced by it was as substantial as that produced by the raw virus. Provided that this critical or effective dose was given, the im-

munity was equally good whether the route by which it was administered was intracutaneous, subcutaneous, intravenous, or intratracheal. If the lymph was heated above 55° C. however—for instance, to 65° C. or over—its prophylactic value was greatly reduced. The time of advent of the immunity was much the same with the heated virus as with the raw virus.

By immunizing rabbits over a considerable period with increasing doses of the virus, immune serum had been prepared of which 1 ccm. protected against 100 M.V.D. of virus. This antivaccinia serum contained specific antibodies to the virus of vaccinia—namely complement-fixing antibodies, agglutinins, and a fixic antibody that destroyed the virus *in vitro*. Attention so far had been mainly confined to the first two of these antibodies which had been found to be equally specific for the viruses of vaccinia and variola, both of the severe and of the mild type sometimes known as *variolina*. The agglutinin present in this serum produced visible flocculi in suspensions of vaccinia or of variola virus that could be seen with the naked eye or with a hand glass if the tubes were exposed for twenty to twenty-four hours at 55° C. Thus the presence of either vaccinia or variola virus could be detected by a macroscopic agglutination test that appeared to be quite specific, and the complement fixation test could be used to check the result. As controls with varicella and other material had proved negative this reaction appeared to be quite specific, and was available for the diagnosis of variola by detecting the presence of that virus in material from the pustules. [Photographs of tubes showing this agglutination reaction with both vaccinia and variola (Clouster) viruses were shown on the screen.] When examined under the dark-field microscope these flocculi thrown down from vaccinia or variola virus by the agglutinating serum were found to consist of oval bodies closely resembling those described by Mr. Brunard in the case of Dr. Gie's cultures of cancer virus.

Some experiments made to determine the effect of gravity and of centrifugalization on the vaccinia virus indicated that it was particulate. The virulence test was far more delicate for revealing this action than the complement fixation test. The Berkefeld filter caused both these reactions to become negative, but in some later experiments evidence had been obtained occasionally of the passage of both vaccinia and variola virus through the filter after the suspension had been kept for several weeks in the cold store before being filtered.

As variola virus reacted specifically with antiovaccinia serum in the complement fixation and agglutination tests, there was good reason to believe that both tests could be employed to assist in the diagnosis of variola.

The final part of the communication dealt with the relative permeability of various surfaces of the rabbit to the virus of vaccinia. Evidence was adduced to show that under natural conditions and in the entire absence of trauma the nasal mucosa was more permeable than the other surfaces by which test was made. The ocular conjunctiva and the external auditory canal were also permeable, but far less so than the nasal mucosa.

The procedure used to determine these points was to administer falling doses of virus to these surfaces, and after an interval of ten days to determine the degree of immunity to vaccinia. On application of vaccinia virus to the nasal mucosa the rabbit after an incubation period of six to eight days developed an acute nasal catarrh with mucopurulent discharge, which during the first day contained the virus of vaccinia in large quantity. This observation seemed to link up vaccinia virus with the causative agent of influenza.

As the nasal mucosa was so permeable to the virus, the value of this route was tested for prophylactic purposes. It appeared that when the effective dose of virus heated to 55° C. was applied intranasally, immunity of a substantial degree followed.

In some subsequent remarks Dr. Gordon said that bodies somewhat resembling those described by Mr. Brunard had been seen by him in the case of flocculi thrown down by the action of precipitins. But whether this was merely a superficial resemblance or not he could not say.

The following is a summary of this contribution to the discussion.

Routine Method followed

- (1) No ordinary microscope used, except to exclude contamination from bacteria (for dark background microscope see later)
- (2) No attempt at culture *in vitro*
- (3) Animal experiment and immunological methods only used so far, and both in quantitative manner throughout

Procedure employed

- (a) The method of dilution of virus 1 in 10, 1 in 100, etc., and titration of rabbit's skin to find end-point described
- (b) The method of preparing suspension of virus from rabbit's skin for use as antigen when preparing antiovaccinia serum was also described. As rabbits were also used to provide antiovaccinia serum, only virus antibodies appeared in their serum when prepared with this antigen.

The contribution was illustrated by lantern slides as follows:

- 1 Relative potency of various specimens of calf lymph M.V.D. comparison
- 2 Disinfectants. Potassium permanganate has a very powerful destructive action on the virus
- 3 Effect of heat. The virus attenuated by thirty minutes at 55° C.
- 4 Active immunity. Comparison of raw and attenuated viruses, for prophylactic purposes. Importance of giving a certain critical dose of attenuated virus in order to produce a substantial degree of immunity. Effect of this dose by various routes. Time of advent, and duration of the immunity.
- 5 Passive immunity
- 6 Specific antibodies formed against vaccinia virus comprise (1) Complement fixing bodies (2) Agglutinin (3) Lysin. This last at present not adequately studied.
- 7 Application of these antibodies—that is, complement fixing—and agglutinin (also of virulence) to determine abundance of vaccinia virus in suspension and thus to determine the effect thereon of—

Grav. %	} Virus is particulate and mostly retained by filter	Result
Centrifuge

Variola

- 8 Antiovaccinia serum reacts as well with variola virus as with vaccinia (complement fixing and agglutinin). Therefore, this antiovaccinia serum can be applied to diagnose variola by detecting the presence of this virus in a suspension of the contents of the pustules or of scabs (employing both complement fixing and agglutinin tests). Confirmed by material from altogether five variola outbreaks. It is specific (vide negative results from six varicella outbreaks, etc.).
- 9 Result of saturation of agglutinin of antiovaccinia serum by vaccinia virus, variola virus, and varicella virus, respectively shown. Vaccinia and variola viruses absorb both vaccinia and variola agglutinins. Varicella absorbs neither of these agglutinins.
- 10 Natural permeability (that is, without trauma) of various surfaces of the rabbit to vaccinia virus, as proved by subsequent immunity. The nasal mucosa is the most permeable of the surfaces. On nasal infection the rabbit after an incubation period of six to eight days, develops a condition of catarrh with a mucopurulent nasal discharge which during the first day contains the virus of vaccinia in great abundance.

Conclusions

- 1 Vaccinia and variola viruses are both particulate, and largely held up by the Berkefeld filter
- 2 Their presence and abundance can be measured, within limits, by the quantitative virulence tests, also by quantitative serological methods—that is, complement-fixing and agglutination tests—with antiovaccinia serum
- 3 Active immunity can be produced to vaccinia with either attenuated or killed virus, provided the dose is sufficient

- 4 A fair degree of passive immunity is possible.
- 5 The capacity of vaccine to excite acute catarrhitis up to the virus with that of influenza.
- 6 Flocculi derived from suspensions of virus or variously prepared agglutinated and composed, and dark-background microscope, of spheroidal bodies closely resembling Barnard's found in cancer cultures. Apparently similar bodies, however, have been found in flocculi from precipitation action—that is, in flocculi thrown down from serum of man or of horse when these are brought in contact with homologous antiserum prepared from the rabbit. The resemblance, however, may be only superficial. Further investigation has not yet been made, the immunity and serological side has been the chief line of research so far, and macroscopic agglutination has fulfilled the requirements so well and behaved quite specifically.

IV

J. F. MCCARTHY, M.D., D.Sc. (Ed.),

Director of Research and Pathological Services, Metropolitan Asylums Board

Dr. Gyr's paper is of great interest to me because he has given expression to thoughts that have occurred to me while working at filterable virus. Dr. Gyr is extremely fortunate in being able to work at animal diseases, in which the natural infection can be studied under experimental conditions in its proper host. The urgent need for definite information as to the biology of the so-called filterable viruses has been frequently emphasized, and Oltshy, realizing the difficulties attending the investigation of human diseases, turned to the vegetable kingdom and studied the virus of mosaic disease of tobacco and tomatoes. He eventually succeeded in culturing the virus in an infusion of tomato leaves. Our future knowledge of the ultra-microscopic viruses will not come from the investigation of human diseases but from an experimental study of animal infections.

I have recently been working on four diseases the incitants of which have been classed as filterable viruses—namely, influenza, measles, common colds, and febrile herpes—and I must confess that the results of my labours on the first two have been disappointing. Typical clinical influenza cannot be reproduced in the rabbit, although there is a reaction in this animal akin to the human disease which may be interpreted as an experimental infection. Measles has been disappointing, and I have not yet satisfied myself that I have produced any definite criterion of the experimental disease in animals. Oltshy and I, working at common colds, were fortunate in obtaining human volunteers, but this is not possible with exanthematous diseases such as measles, rubella, and chicken-pox, as the susceptible individuals are not adults but young children.

I am glad Dr. Gyr has emphasized that filtration does not depend on the actual size of the pores of the candle. Filtration appears to be a problem in colloidal chemistry, in which case the hydrogen-ion concentration would be an important factor.

With regard to the failure of the filtration of brain tissue from rabbits dead from herpetic encephalitis, I ascribe that, not to the virus being attached to the brain tissue, but to the fact that the host material from the brain is in a state of colloidal suspension and the pores of the filter are clogged by it. If, however, a small piece of the infected brain be placed in a tube of 2 per cent glucose broth and incubated for forty-eight hours at 37° C., the virus passes out of the brain tissue into the surrounding broth. If this clear broth be now filtered through a Berkefeld candle, it is found that the virus passes through quite easily with apparently no loss in its infective power. I was unable to detect any difference in the infectivity of different layers of the virus-containing broth by centrifuging, but I did not employ such high speeds as Dr. Gyr, and, moreover, the infective dose of the fluid was very small, 0.001 c.c.m. in some cases being sufficient to bring about a fatal issue when injected intracerebrally into a rabbit. Examination of the sediment after prolonged centrifuging of the broth containing the virus failed to reveal any forms which could be identified as organisms.

The difficulty of obtaining artificial growths of the filter-

able viruses is very great. The infective dose is often small and there are many failures to become immune before it can be titrated that there is any definite multiplication of the virus. I have a uninfected herpes virus in the third subculture in a medium the basis of which is malted barley in extract and kept it alive outside the body in the medium at 37° C. for so many days, a longer without culture, the virus does not survive in broth at 37° C. for more than six days. In one instance the fourth subculture was infective (twenty-one days outside the body). These experiments do not necessarily mean that the virus actually multiplied. Probably the conditions for survival were favourable, and the infective material in the subcultures was merely carried over from one to another in each medium. The results indicate, however, that it may soon be possible to cultivate the virus of febrile herpes in artificial media.

Cultures in Smith-Noguchi medium does not necessarily mean growth, as this is frequently seen in sterile un inoculated control tubes. The occurrence of clodders depends on the amount of aseptic fluid—the higher the aseptic gravity the more likely it is to occur. As the clodders show its just above the surface fragment, the character of the layer of concentration around the tissue is probably responsible for its occurrence. Personally, I feel that Smith-Noguchi medium except for the growth of "globoid bodies" of poliomyelitis and *Bacterium paratyphosus* is unsuitable for the cultivation of filterable viruses. I do not often find the virus disappear more rapidly from a tube than from a saline or broth control.

I agree with Dr. Gyr as to the difficulties of examining sterile filtrates microscopically for organisms on the limits of clarity, and particularly films made from media containing just a small amount of fluid, and stained by Gram's method. I have found well ripened methylene blue more reliable. This was particularly noticed in attempts to cultivate the virus of common colds in Smith-Noguchi medium. Filtered nasal washings were used and proved to be infective by inoculating a human volunteer at the same time as the Noguchi cultures. After seven to ten days incubation, films were made and stained by Gram's method. In some preparations minute round bodies were noted, just visible, they had a definite contour and appeared to possess a definite morphology. Subcultures of these bodies in Noguchi medium frequently showed similar forms, but appeared as though these bodies were organismal and capable of cultivation. The examination of incubated but un inoculated control tubes, however, showed similar appearances. These minute bodies were thought by Foster to be the crucial organism of common colds, but the fact that identical appearances can be found in uninoculated culture tubes proves these small "globoid bodies" to be artefacts.

As animal experiment is the only reliable test for the presence of filterable viruses the importance of adequate controls cannot be overestimated. Not only is it necessary to cultivate the filtrate on various enriched media both aerobically and anaerobically, but it is essential that the type of receptors which the animal shows is due to the presence of the inoculated virus. This is particularly important in attempting to transmit diseases peculiar to the human race to experimental animals. Rivers and Tillett in attempting to produce experimental chicken pox, Miller when working on acute rheumatic fever, and myself when searching for a filterable virus in scarlet fever, all obtained by continued intratesticular passage what is now considered to be a hitherto unknown rabbit virus, the virulence of which has been enhanced by continuous passage. When the virus obtained by the injection into rabbits of blood from scarlet fever patients failed to exhibit any serological relationship with the disease, the experiments were repeated, using normal human blood. A similar virus showed itself at the third testicular passage, showing that in the previous experiments the virus was not, as it was thought to be, etiologically connected with scarlet fever. This experience demonstrates that when animals are inoculated with material from a disease from which they do not normally suffer, a reaction on the part of the animal is not necessarily due to an infective agent introduced in that material, and one should be cautious in drawing any conclusions from such experiments until full and complete controls have been made.

Work on filterable viruses is technically difficult, full of pitfalls, and fraught with disappointment, and where the disease cannot be communicated satisfactorily to lower animals progress must be necessarily slow.

Dr GYE is to be congratulated on the valuable facts he has obtained and for the advancement he has made in this obscure field of work.

GENERAL DISCUSSION

Dr J S MINSON remarked that Dr GYE said that there were two factors in the causation of malignant growths (1) a primary factor—a filterable virus, and (2) a secondary factor—specific. Dr Minson asked whether this secondary factor was a reaction of the animal to the primary virus, and, if so, how did this become a primary cause, and how did this affect the development of benign growths as distinguished from malignant growths?

Dr GYE answered that he did not know.

Dr J G STEPHENS asked Mr BRINDLEY if he had ever noticed any response by Dr GYE's virus to the ultra-violet radiation employed in microscopy. The wave length used, of the order of 257μ , was well within the region to which living organisms were susceptible. If the present virus reacted similarly it might perhaps be possible to influence a tumour by means of fluorescent ultra-violet light excited in a tungsten salt, say, by means of x-rays. Similar effects with other organisms and other fluorescent substances—for example, quinine and cosine—were, of course, well known.

Mr BRINDLEY said, in reply to Dr STEPHENS, that the question of the influence of ultra-violet light on the organism was dealt with by him in the recent paper he had published in the *Lancet*. Changes certainly occurred in morphology as the result of exposure to ultra-violet light, but his whole method was designed to avoid such errors by a very short exposure.

Dr J BARROET ANDERSON inquired whether it was not now accepted that the infection of human tuberculosis was a filter-passer, and that the shed granules of the bacillus (which gave the bacillus its bearded appearance) were infective and filter-passers. Because, if this were accepted, it was obvious that not every culture of that micro-organism would contain these granules, and therefore not every culture contained the filter-passing infection. Dr BRINDLEY ANDERSON inquired further whether it was not accepted that cancer was a combination of two different pathological cell conditions, both of which were recognized as due to the presence of micro-organisms: first, cell multiplication, the most common instance of which was the granulation tissue formation in septic wounds; secondly, phagocytosis, common instances of which were the macrophages of the lymphatic system, and the analogous phagocytic bodies arising from the endothelial cells detached from the lining walls of blood vessels when the blood was heavily infected. He asked whether the cancer problem was not that of discovering what micro-organism or organisms could produce this combined result of cell multiplication with phagocytosis, and whether such a micro-organism might not be both a filter-passer and detectable under the microscope, as in the human tubercle bacillus.

Dr GANROW asked if Dr GORDON had found any immunological evidence of difference between the virus of classical small pox and of the mild variety called alastrim.

Dr GORDON replied that this question was answered in his report to the Medical Research Council (now in the press).

Dr JOHN MENTON said that as Dr GORDON stated that vaccinia virus became more easily filterable after several days' keeping in cold storage, he would be glad to know what in Dr GORDON's opinion were the factors influencing this.

Dr GORDON stated that probably the answer was that the cells were autolysed and the virus was liberated from the cells.

Dr MARK CORIANS said I have been engaged upon the question of the filterability of the virus of vaccinia for some years, and I confess that my attempts have invariably ended in failure: the filtrate has always proved to be virus free. For these experiments potent glycerinated calf lymph has been employed, the filtration being through baked porcelain or siliceous earth candles. The action of such filters is by no means simple: the nature of the filtrate yielded depends upon several factors. A recently baked candle displays marked adsorptive properties and is capable of removing many substances including dyestuffs and toxins, from the passing fluid: if the candle be reduced to fine powder and simply shaken with the liquid the same properties are seen. In addition, the gelatinous layer of material which sometimes forms upon the external surface of the candle is of itself capable of acting as a filtering agent: arresting not only visible particles but also colloidal substances. At this stage the act of filtration is slowed and pressure filtration much aggravates the situation: devices become necessary to clean the clogged surface. Such a gelatinous layer is of advantage in industrial processes, in which filtration is essential and it is utilized in the beer and mill industries. We are all of us familiar with the fact that the constant reponing of a turbid fluid after filtration through the same filter paper in a funnel eventually leads to considerable clarification of the filtrate. It ought to be more widely appreciated that filter candles vary in texture and efficiency, not only between one another, but also with regard to each individual candle. Filter candles are by no means of uniform texture. This is due to the process of manufacture, the candles being baked in batches in a furnace with flames playing upon the exposed surfaces of the batch. The flame-exposed surface of the candle is scorched and becomes more brittle than the portions not so exposed. This unevenness in texture can be readily appreciated by connecting up a bicycle hand pump to the interior of a candle which is immersed in water. You have only to pump and to watch the variations in size and rate of escape of the bubbles of air. Judged by this standard the proportion of irregular and defective filter candles is high. Most workers will agree with me that filter candles can be very treacherous and disappointing as laboratory instruments, particularly when used for the purpose of advanced research, and it would be a help to all laboratory workers if standards as to texture and constitution of filter candles were laid down.

The President of the Section, Dr LEDINGHAM, expressed his appreciation of the serological work carried out by Dr GORDON with the virus of vaccinia, and asked for further information with regard to the infection of animals through the nasal mucosa, especially in view of the belief that small-pox entered the system by the respiratory route. He referred to his own researches, which had shown that the viruses of vaccinia and of virus molluscum did not attack primarily the Malpighian elements of epidermis or epiblastic tissue generally, but exerted their primary and main action on the reticulo-endothelial tissues wherever situated. Even in the cornea, though the origin of the so-called Guarnieri bodies was still in dispute, the main action of vaccinia virus was on the mesoblastic elements in that region represented by polynuclear cells coming from the vascular region at the corneo-scleral junction, and the endothelial cells lining the lymph spaces of the cornea. Further, not only could the vaccinia virus be recovered from testicle or brain, but also from organs such as the spleen. For example, five or six days after direct intrasplenic inoculation of virus, in emulsion of spleen tissue proved highly virulent. His attempts to filter the virus had consistently failed so far. He was now testing the oedema fluid which could be readily collected in a capillary pipette from intracutaneous lesions at the height of the reaction after blebbing the animal to death under ether. As much as 0.5 c.c. could be collected from two or three well developed intracutaneous lesions after incision with razor blade and slight pressure with forceps. The fluid so obtained was highly potent and lent itself readily to filtration experiments which were now under way. With reference to Dr GORDON's experiments with heated vaccinia virus, the President remarked that the use of vaccine entirely free from contaminating organisms would doubtless be desirable provided it was efficient as an immunizing agent. So far he

understood that heated lymph were poor antigens and very inferior to the live virus. Tevdtit and Nicolai's live vaccinia virus prepared from rabbit brain was an important advance and some recently reported trials had shown a very high percentage of takes in primary vaccination of children.

In reply to a question by Dr. C. Snow with reference to material from cases of the prevailing mild small pox, the PRESIDENT said he had succeeded in transferring three samples of such material sent by Dr. C. Snow direct to rabbits by intracutaneous inoculation. These reactions were always annulled when the small pox virus was digested previously to inoculation, with virucidal serum prepared from rabbit hyperimmunized with vaccinia.

THE SECTIONS

BRIEF SUMMARY OF PROCEEDINGS

ARRANGEMENTS have been made to publish, during the next few months, full reports of the discussions in the Sections of the Annual Meeting at Bath, Maine, the notes printed below will enable members who were not present to gain a general view of the proceedings. Any errors to which attention may be drawn will be corrected in the full reports.

SECTION OF MEDICINE

Wednesday, July 22nd

RHEUMATOID ARTHRITIS

AFTER some opening remarks by the Chairman, Lord Dawson, Sir Humphry Rolleston opened a discussion on rheumatoid arthritis, its causation and treatment. For the purpose of the discussion rheumatoid arthritis was taken to cover the group of chronic joint infections of uncertain origin, excluding advanced osteoarthritis. Dealing first with etiology, Sir Humphry Rolleston discussed the possibility that disordered metabolism might be the sole cause of at least one group of these cases, as was suggested by Sir Archibald Garrod. Various metabolic disturbances had been suggested—a lowering of the sugar tolerance, a thyroid, ovarian, or pluriglandular inefficiency, and recently H. K. Thompson had described two types of arthritis associated with hypo- and hyper-thyroidism. It was, however, difficult to exclude the possibility that a chronic infection might be the underlying factor both of the endocrine and the arthritis disorder. Turning to an infective origin, Sir Humphry Rolleston mentioned the various forms of oral sepsis, teeth, gums, and tonsils had all been incriminated. In pyorrhea the infective agents were discharged into the alimentary canal and so set up secondary infection in the tonsils, gall bladder, intestines, and appendix, whereas apical infection of the teeth in which absorption by the blood occurred was more likely to result in joint infection. Intestinal auto-infection had been urged as a cause of chronic arthritis by Sir Archibald Lane, and Mitchell had developed this view on bacteriological lines, finding a long-cultured streptococcus of characteristic glycolytic character—a fact of great interest in connexion with Pemberton's successful results in restricting carbohydrate intake. Some observers had associated achylia gastrica with chronic rheumatoid arthritis, suggesting that the absence of gastric hydrochloric acid favored a bacterial infection. Infections of the genito-urinary tract did not play any prominent part, and infection of the respiratory tract had attracted little attention in this connection, but Potter and Lenche's view that the commonest form of chronic infective arthritis was due to toxaria and start tuberculous foci acting on the joints, though receiving no support in this country, was widely accepted in France. In considering the criticism that sources of chronic sepsis were frequently present without producing rheumatoid arthritis, it was necessary to remember that like, as in other infections, the soil as well as the seed must be an important factor. Defects of constitution of the individual, or an acquired susceptibility, was the result of disease or trauma, might well provide the other necessary factor for joint infection. On the other hand, in many cases no source of sepsis could be found, but the infective focus might easily be in some closed situation so deeply hidden as to defy detection. Another point for

discussion was how far the clinical phenomena could be explained on anaphylactic ground. Might a joint once infected acquire a hypersensitivity and then give an anaphylactic response to a toxin reaching it from a subsequent infection elsewhere? Various microorganisms had been isolated and held it possible for the disease, and the would be in that the condition was not a specific one, but was due to a number of disease clinically much alike. Frequent but primarily preventive possible sources of sepsis must be removed; antitoxins, not stored vaccines should be used. Thyroid and parathyroid extracts both had their advocates and a remedy had been employed. Pemberton advised the restriction of carbohydrate in the diet as a great assistance to other methods. Hydrotherapy and ultra-violet radiation had given gratifying results probably by raising the resistance to infection or by speeding up metabolism. Protein shock therapy had also been employed with some success. Mr. W. R. Adland said that it was important to realize that pyorrhea did not ever entirely drain and open sepsis seemed to be tolerated for years without apparent harm. The gastric juice did not always defeat the harmful effects of bacteria from the mouth, it might liberate an endotoxin. With regard to treatment, bridge crows and dead teeth were all to be condemned. Dr. Rupert Watkinson observed that from his experience at Bath the percentage of cases cured by removal of septal foci was small, and when the foci had been dealt with, splint treatment would nearly always give very definite and useful improvement. Sir Robert Jones confined his remarks to the prevention and correction of deformities, and he stressed on the fact that if practitioners would use the simple measures for preventing deformity in the early stages they would remove all need for operation by the orthopaedic surgeon.

Professor Osgood (Harvard) said he was looking for some link between the toxic and metabolic factors, and suggested that it might be found in allergy. He ended with a plea for co-operation with the orthopaedic surgeon, so that deformities might be prevented. Professor Cavendish (Athens) gave the results of his work on the excretion of sulphur in the urine in rheumatoid arthritis. The increase of neutral sulphur found was not due to increased protein metabolism, nor was it due to destruction of cartilage. It appeared to be the result of an inability of these patients to oxidize sulphur. Dr. J. M. H. Munro said that the blood picture indicated a general infection in 85 per cent of cases, and that serological tests confirmed to some extent the streptococcal origin. Mr. A. G. Timbrell Fisher classified chronic arthritis on lines of morbid anatomy, and emphasized the need for considering the physiology of the nutrition of the joints. Sir William Wilcock supported the view that the vast majority of cases had an infective origin. Sir James H. said that the immediate cause of rheumatoid arthritis was acid, due to acid fermentation in an enlarged stomach and consequent decalcification. Lord Dawson, in concluding the discussion, said that infection clearly played some part in the etiology of the disease, how great was that part? He thought that much further information might be obtained along the lines mentioned by Professor Cavendish by investigating the individual's power of resistance.

Thursday, July 23rd

HYPERTENSION

The second session was held with Professor T. R. Elliott, F.R.S., in the chair, and the discussion was on hypertension. Professor Stirling in his opening paper dealt with the physiological factors that must be taken into consideration in discussing a permanently raised blood pressure. The most essential factor must be the control exercised by the vasomotor centre. The vasomotor centre regulated its own blood supply by increasing or diminishing the amount supplied to other parts. In hypertension there was a permanent setting of the blood pressure at a higher level, and that must mean that at the normal pressure in the circle of Willis the vasomotor centre was not receiving sufficient blood for its requirement. There were several ways in which such a state of things might arise—for example, loss of elasticity in the arteries, constriction of the vessels supplying the vaso-

molar centre, spasm of the arterial wall, changes in the capillary wall affecting the flow, or an altered permeability. Alteration in the capillary wall with consequent effusion into the pericapillary lamellae might well explain the toxic condition seen in mæmia and the toxæmia of pregnancy. It was impossible to exclude the question of the part played by the kidneys, and there was considerable evidence that progressive occlusion of the renal vessels might give rise to progressively increasing arterial blood pressure. It must be remembered, too, in this connexion that complete obstruction of the renal circulation would not by itself cause a rise of blood pressure, it could only do it by the indirect results of the occlusion in the vasomotor centre, possibly the retention of substances which should be excreted with the urine had a direct effect on the vasomotor mechanism.

Lord Dawson assumed that hypertension was a disease *suæ generis*, and he approached the subject through the avenue of youth. The systolic blood pressure between the ages of 20 and 45 was 115 to 130 mm, the diastolic 75 to 80. A systolic pressure of 140, or a diastolic pressure of 90, between these ages were to be considered with umbræ. The normal blood pressure, however, varied in the healthy body within comparatively wide limits, and the higher civilization went the broader these limits would become. Hypertension might be merely an exaggeration of a quality normal for the individual. He had investigated a series of 650 school children between the ages of 10 and 17. Of these, 52 (8 per cent) had a systolic blood pressure of over 130. This hypertension was not associated with any particular type of child, examinations alone did not send the blood pressure up, but in one group of children who were entered for the higher examinations the numbers with high blood pressure were two and a half times greater than in the other groups, this he considered to be due to a continued state of intentness and anxiety, or an existing state of mind intensified by striving. In some temperaments the anxiety would relax in the intervals, in others it would not. Here was the opportunity of preventive medicine, evidence of persisting vasoconstriction being a danger signal. Lord Dawson gave further details of some of this group of 52 children, showing that they were passing into the realm of disease, the most definite change being cardiac hypertrophy. With cases so mild no confirmatory pathological evidence was available, but he concluded with a description of one case in which such evidence was forthcoming.

Dr McGee (Philadelphia) pleaded for the help of the general practitioner: the early and continued study of the blood pressure was essential, and only the general practitioner was in a position to make it. He raised the question of organic causes in all cases, and discussed the effect of endocrine disturbance, noting the variation in blood pressure sometimes seen at puberty and the menopause. Dr Betty Shaw asked, Was high tension an affair of the arteries or not? Arterial disease was certainly a frequent accompaniment of these cases, but there was also so much that was toxic that he thought the time had come to abandon the arterial view, and that there was sufficient clinical evidence of the toxic origin of permanent high tension. The toxic bodies with pressor action that were known to them were very few, a pressor substance had been obtained from the cortex of the kidney, but in many cases of hypertension the cortex of the kidney was quite undamaged. He concluded with the clinical details of a case illustrating hypertension of toxic origin.

Dr Otto May gave the statistics obtained by a large assurance company as to the relation of high systolic blood pressure and expected mortality, they confirmed the view that high blood pressure was unfavourable to longevity. But it was very rash to apply these statistical findings to individual cases. Dr Geoffrey Evans said that structural changes in the medulla were insufficient to account for the condition. He described the morbid anatomy which was quite characteristic and enabled the disease to be diagnosed in the post-mortem room. It was therefore a definite entity. Dr Humphris emphasized the value of electrical treatment, and Dr Salisbury Shupe gave particulars of a series of 500 cases observed in the seventh decade of life.

Friday, July 24th

ENDOCRINE THERAPY: ITS USES AND ABUSES

Dr W Langdon Brown, opening a discussion on the uses and abuses of endocrine therapy, said that rational endocrine therapy must be based on three criteria: (1) the gland must form an internal secretion, (2) the active principle of this secretion must be capable of extraction, (3) a method of administering this extract must be found which will admit of its utilization in the body. In only a few instances were these criteria fulfilled, so that clinicians had been compelled to resort to empirical methods. In the case of thyroid extract all three criteria were satisfied. The efficacy of thyroid medication was universally accepted and needed no further emphasis. Parathyroid extract increased the calcium content of the blood with a sedative effect on nervous tissues, and it promoted healing from the effects of chronic sepsis: it was useful in tetany, and sometimes had proved helpful in chronic gastric ulcer, spine, and varicose ulcers. The medulla of the adrenals undoubtedly produced a very active extract, and although there were some who declined to connect the effects of a hormone with those of stimulation of the post-ganglionic fibres, Dr Langdon Brown preferred to accept the mass of evidence pointing to adrenalin as a general sympathetic stimulant which could be drawn upon in an emergency. It was of little, if any, use as a substitute for the chronic adrenal lack in Addison's disease. The pituitary gland was composed of various parts: the anterior lobe was concerned with growth and sexual development, the posterior lobe had a marked effect on plain muscle and on the excretion of water from the kidney. Dr Langdon Brown then put the question: Was the administration of pituitrin merely the exhibition of a drug of known pharmacological properties, or was it an attempt to replace or reinforce the normal functions of the posterior lobe? This question went to the root of the controversy on endocrine therapy. The clinician believed that the pituitary had an important association with the reproductive processes, and he brought forward a number of clinical and experimental observations in support of the clinician's view. Intramuscular injection of 1/2 to 1 c.c. of pituitrin stimulated the muscles of the heart, intestine, and uterus, and controlled polymyria. With regard to pancreatic extracts, the efficacy of insulin was beyond doubt, unfortunately much prejudice had been aroused amongst the general public against it, but it was emphatically untrue that a patient who had once started it would be worse off than before if it were discontinued later. As to the value of other extracts Dr Langdon Brown was sceptical, but he was hopeful that an active ovarian extract might soon be available.

Professor Sæle Vincent remarked that in spite of repeated attacks on the uncritical employment of animal products as drugs, the sale of worthless preparations went on apace. The expression 'endocrine therapy' was only rightly used when it was possible artificially to replace the internal secretion of some ductless gland. In discussing the value of endocrine therapy there were two difficulties: first there was the difficulty, common to all branches of therapeutics, of distinguishing between *post hoc* and *propter hoc*—rigid controls must be instituted, the second difficulty lay in the fact that endocrine therapy rested largely on a priori or on theoretical considerations. It was based on the view that all organs manufacture and pour into the circulation an internal secretion whose function it was to influence the metabolic activities of the body, but there was no reliable evidence to support such a view. Although extracts from most organs and tissues produced no noticeable physiological effect when given by the mouth, yet when given subcutaneously or intravenously some influence might be produced. Intravenous injection of tissue extracts in general might in particular produce lowering of the blood pressure. These effects, however, were not specific and had nothing to do with any internal secretion. Thyroid preparations were universally recognized as among the most valuable of drugs: dried thyroid substance was probably the surest, and when there was a low basal metabolism there was an intelligent reason for its administration. They were ignorant as to the functions of the parathyroids, and the results of parathyroid medication were very uncertain, but Collip claimed to have

that came to operation during the last five or ten years, although the missed statistics from seven hospitals presented by Mr. Souttar showed that the mortality for all forms of acute intestinal obstruction was still deplorably high, ranging from 51 per cent in volvulus down to 16 per cent in cases of inguinal hernia, whereas the mortality for the operation of radical cure of strangulated hernia was less than 1 per cent. The question of anaesthesia received attention, and local anaesthesia, which largely did away with the risks of lung complications, was advocated. On the question of the education of the public, in order to induce them to present themselves at an earlier stage of this disease, there was some difference of opinion, since it was held by Mr. Grey Turner that the medical profession itself was at least as much to blame for the reluctance and tardiness with which they came to a diagnosis, as were patients themselves. An instance of the value of the education of the profession was provided by the speaker in his reply, when he explained that the striking success he had obtained in the operation for intussusception, in which his mortality was but 3.7 per cent (as against 2 per cent in the missed statistics), was due to his special interest in the subject and his continued efforts to instruct the practitioners with whom he came in contact.

SECTION OF OBSTETRICS AND GYNAECOLOGY

Wednesday, July 22nd

PELVIC CANCER

THE proceedings of this Section were opened by the President, Lady Barrett, who claimed that they could seriously have chosen a more important subject to discuss than that of pelvic cancer in view of the steadily increasing mortality from malignant disease, whereas the mortality rate of practically all other diseases had been steadily diminishing. The opening paper, on the problem of uterine cancer, was then read by Professor B. P. Watson (Edinburgh). Professor Watson explained that though nothing new could be said on the subject, nevertheless constant reiteration was necessary if the public and the profession were to be thoroughly convinced of the responsibility which rested upon doctor and patient alike in the effort to diminish the great loss of life resulting from this disease. The proper education would result in such a diminution had long been realized. The fact that it had not done so was justification for his paper. Professor Watson then quoted statistics from England, Scotland, and America to show the frequency of the disease and its high mortality rate. In seeking to effect a diminished incidence of the disease they should not be discouraged by the fact that the ultimate cause was not yet known. It was often possible to reduce the incidence of a disease by controlling one factor which appeared to play a part in causation. There was one factor in cancer that was so constant that it must be recognized as one of the etiological factors, and that was irritation, and this was a factor which could be controlled. Local irritation could be reduced, first, by abstention from all procedures which might tend to produce deep lacerations, and secondly, by the thorough treatment and repair of existing lesions. Professor Watson entered a strong plea for the more frequent and thorough operative treatment of cervical lacerations. In addition, two other things were necessary to bring about a diminution in the mortality from pelvic cancer—the education of the public in the early signs and symptoms, and the education of individual members of the profession in the importance of a most thorough investigation of any woman seeking advice on account of these symptoms and signs. Along with a publicity campaign for the information of women regarding the symptoms, emphasis should be placed on the fact that cancer, if detected early, was a curable disease. Professor Watson quoted statistics of the percentage of operable cases seen in various clinics at home and abroad, and claimed that propaganda, especially in France and Germany, had led to a far greater number of early cases to present themselves for treatment abroad than did so at home. Professor Watson touched upon the symptomatology of cancer of the cervix, especially in relation to the duration of symptoms and the age incidence. He emphasized that what the student had to be taught was the

recognition of the early case, and he explained his own practice in this respect. The early cases showed a high percentage of cures, whether operation or treatment by radium was the method of choice. He reviewed some of the recent statistics, and expressed the opinion that for border-line and advanced cases radium treatment was the only one to hold out any hope, but in regard to cancer of the body operation appeared to give a better chance than radium. Professor Watson spoke strongly in favour of educating the female public more fully in the knowledge of their own anatomy and physiology. He had found nothing but good had come of this knowledge on the other side of the Atlantic.

Mr. Victor Bonney (London) dealt with the surgical treatment of malignant disease of the pelvic organs. He had no doubt that surgical treatment remained the treatment of election for the majority of cases, and he would limit his remarks to a review of his own experience and results. If the spread of cancer were by tissue infiltration only, a local excision just outside the limits of the growing edge would be all that was required. Lymphatic permeation was very much more rapid, so that in these regions the line of excision must be carried as far outwards as the anatomy of the parts and the endurance of the patient would permit. The operation which fulfilled these requirements they owed to Wertheim, whose services to humanity he did not think had been properly recognized. He personally had performed this operation 300 times, but in order to obtain figures based on a five years freedom from recurrence he intended to quote from the first 192 cases only. He estimated his operability rate—that is, the ratio borne by the number of cases operated upon to the total number of cases seen in the same period—at 63 per cent. He had operated upon every patient in whom there appeared the slightest chance of being able to remove the growth. Amongst his series were many cases which had been sent away as inoperable from institutions of the highest repute. In general the only basis to the accomplishment of the operation he had recognized had been deep and extensive involvement of the bladder or bowel or involvement of both ineters to the extent of producing bilateral hydronephrosis. It was often impossible to judge whether a case was operable or not until the abdomen was opened. Cystoscopy would help to establish whether the bladder was involved or not. Another important point was pain. Cases without pain were almost invariably operable, for pain was nearly always due to involvement of the extracervical tissues, and its absence would indicate that the growth had not spread beyond the cervix. The operation he performed was as drastic as he thought it was possible to perform and yet give the patient a good chance of recovery. In addition to the uterus and appendages together with the parametric and paravaginal tissue, the glands and cellular tissue occupying the obturator foramen and the glands along the external iliac vessels he now removed the whole of the vagina in most cases. His results in 192 cases were as follows: Died of the operation, 32; died of recurrent growth, 70; died of other disease, 5; lost sight of, 7; well after five years, 78. Mr. Bonney then considered these figures in more detail. Of 60 patients with carcinomatous glands who recovered from the operation, 33 per cent were well five years afterwards, while of 100 patients whose glands were not carcinomatous and who recovered from the operation, 58 per cent were well five years afterwards. In addition he had prolonged the lives of 87 or 60 per cent of the 160 patients who survived the operation. In regard to pre-operative irradiation Mr. Bonney insisted that the preliminary treatment made the operation far more formidable on account of the intense fibrosis set up. Neither did he advise post-operative irradiation. The results of surgical treatment would be greatly improved if performance of this very extensive operation was confined to those only whose opportunities had allowed them to become expert at the operation. Mr. Bonney then referred to carcinoma of the corpus uteri and the difficulties in making a correct diagnosis of this condition. He advised a free total hysterectomy except in cases where secondary growth might be present in the cervix or vagina when a Wertheim or a "super-Wertheim" would be necessary. He did not advocate vaginal hysterectomy in these cases.

Mr S J Cameron (Glasgow) limited his remarks to malignant disease of the ovaries and tubes. He said that both conditions were comparatively rare and little could be gleaned from the literature about them. It might be very easy to overlook the true nature of cystic ovarian disease unless all specimens were submitted to microscopic examination. The presence of free fluid in the peritoneal cavity definitely indicated malignancy, and a deterioration of the patient's general condition for a short time previous to examination should arouse suspicions as to the nature of the tumour. In 31 out of 94 cases the ovarian disease was secondary to a primary growth elsewhere, but the size of the secondary growth bore no relation to the size of the primary condition. Carcinoma of the ovary was much more common than sarcoma. Mr Cameron classified his cases into a series of five yearly age groups and constructed a table of symptoms from these—namely, pain, haemorrhage, ascites, general ill health. The statistics of ovarian carcinoma compared badly with those of cervical cancer, and the difficulty of making an early diagnosis was even greater. Perhaps in future early diagnosis might be made possible by means of a biochemical or serological test. Carcinoma of the Fallopian tubes was very seldom met with. Mr H J D Smythe (Bristol) agreed with Mr Bonney that the most radical operation for cervical cancer was absolutely necessary. He did not favour either pre- or post-operative irradiation. He spoke in favour of panhysterectomy in cases of cervical laceration or hypertrophic erosion. Professor W C Swayne (Bristol) agreed that the most extensive operation possible held out the brightest prospects, but a very expert operator and a very expert assistant were required to ensure success. He agreed that the female public must be educated, but he was a little doubtful about the educability of many women. Students must be thoroughly drilled in the elements of gynaecology and must be taught to regard any deviation from the physiological normal of any given woman as a possible danger signal. Mr Sidney Forsdike (London) did not think that many surgeons could or would undertake the cases which Mr Bonney dealt with. Neither did he think that Mr Bonney's figures would give either patient or surgeon complete confidence that everything was for the best. The risks were too great. Mr Bonney had not told them how he applied irradiation. It was useless to educate the public in the importance of early diagnosis until medical practitioners had educated themselves.

Mr C P Childe (Portsmouth) emphatically agreed with the importance of educating the public and the student. With earlier diagnosis a less severe operation with less primary risk might be possible. Mr Leith Murray (Liverpool) urged that midwives should be better instructed as many women applied to them in the first instance. While not agreeing with pre-operative irradiation, he spoke strongly in favour of post-operative treatment. Another speaker referred to the cost of irradiation to poor-class patients, who would rarely continue treatment on this account. Mr Malcolm Donaldson (London) deprecated either too optimistic or too pessimistic expressions of opinion as to the value of irradiation. Let them confine themselves to facts. Mr Paramore (Rugby) advocated panhysterectomy rather than subtotal in all cases except when the feebleness of the patient contraindicated the more severe measure. Another speaker inquired as to the frequency of the occurrence of carcinoma in the cervical stump after subtotal hysterectomy. Mr Marlow (Toronto) expressed the view that propaganda in Canada was beginning to bear fruit in the greater number of early cases coming under treatment. He spoke in favour of extensive cauterization of the diseased part as a preliminary to radical operation. He urged the importance of thoroughly treating cervical lesions as a prophylactic measure. Dr Larquhar Murray (Newcastle) thought Mr Bonney's results showed the extreme limits to which surgery could go. He agreed with the importance of educating the public, and could not see why much more could not be done on the same lines as had been done already with venereal disease.

Thursday, July 23rd

The subject for discussion was the treatment of inoperable carcinoma of the pelvic organs, and the opening paper

was read by Dr June Heyman (Stockholm). Dr Heyman thanked the members of the Section for the honour shown to him and to his Swedish colleagues in inviting him to address them that day. Ten years ago he said, in speaking of uterine cancer, the word "inoperable" was synonymous with "incurable." It was not until the advent of the method of treatment by radium that real interest was aroused in the cases. Treatment of inoperable cancer of the pelvic organs now meant radium. He proposed to lay before them his natural experience derived from fifteen years' work at the Radiumhemmet, Stockholm. The cases under his care comprised cancer of the uterus, ovaries, vagina, urethra, and vulva. Nearly all the cases they treated had been referred to them from other hospitals, and they had confined their treatment strictly to inoperable cases to gain experience before they had attempted radium treatment upon operable cases. This applied to all cases except cancer of the cervix where the results set out in their last published report had been so striking that their leading surgeons and gynaecologists had given up operating for this condition. They had had in total of 243 cases under observation for five years or longer, in the majority the results were palliative only. Dr Heyman showed a series of tables giving the results of treatment as regards the improvement of symptoms. Two thirds of their cases had regained strength sufficiently to enable them to resume work after undergoing treatment, and 16.7 per cent had remained free from symptoms for five years or more and might be regarded as permanent cures. These cases would have been regarded as hopeless and left untreated without radium. In carcinoma of the corpus the inoperable cases were comparatively few though a number might be clinically, though not technically, inoperable on account of old age, pulmonary disease, adiposity, diabetes. Out of 17 such cases treated by them 10 had remained cured for five years. In regard to ovarian cancer, their results were not good. They had found that cases where an incomplete operation had been performed did better than those in which no operation had been attempted, so that they now advised removal of the ovarian tumour and subsequent irradiation shortly after operation. Cancer of the urethra was very rare, and did not do well with radiation. Cancer of the vulva also gave most disappointing results, cancer tissue in this region being biologically only slightly susceptible to radium, while the parts were nearly always badly infected and subject to chronic irritation. Dr Heyman then reviewed the technique employed in each variety of case. Mr Percival P Cole (London) followed with a review of his experience gained from the Cancer Hospital, London. He assessed the general inoperability rate at about 62 per cent. The mortality rate of operation was about 20 per cent, and the percentage of five-year cures after operation about 28 per cent. Metastases in cervical carcinoma were uncommon, and fully 60 per cent of deaths occurred as the result of effects determined by what remained to the last a local lesion. He personally had no experience of cases treated with radium with a view to rendering them operable, practically all the cases were decidedly inoperable on admission. Mr Cole then quoted statistics of the cases treated at the Cancer Hospital, remarking that 40 per cent were so advanced that no treatment could be given at all. He detailed the technique which they had adopted, and referred to the outstanding contraindications to radium treatment—namely infection, cachexia, and anaemia. Proctitis, cystitis, and fistula formation might follow radium treatment, and such intense fibrosis might be excited as almost totally to occlude the vagina. With improved technique the sequelae were seen much less frequently. Mr Cole tabulated the results they had obtained with radium. Owing to the risk of haemorrhage, he had opened the abdomen, tied the iliac vessels, and applied radium within the peritoneal cavity, and he had been astonished at the good results obtained. The most satisfactory method of applying radium from within the abdomen had not yet been evolved. He commented favourably on the use of x-ray after radium, but had found injections of colloidal copper, platinum, and electro-selenium of no use whatever. He spoke favourably of the extirpative operation followed by the insertion of radium as a means of alleviating distressing

symptoms. Judging their results as a whole, the number of cases which had not benefited to any material extent by radium treatment was large, and their experience at the Cancer Hospital in the treatment of inoperable cases did not warrant them in adapting them to operable cases. Mr Malcolm Donaldson (London) followed Mr Cole, and pleaded earnestly to the whole profession to combine in working out to the utmost the radium treatment of inoperable cancer of the pelvic organs. He referred to the 5,000 deaths yearly from this cause alone, and urged the importance of educating the public so that cases might be recognized in the early stages. Cancer of the cervix remained local for a considerable time, and thus made it extremely suitable for treatment on research lines. Mr Donaldson detailed the technique employed at St Bartholomew's. His conclusions were that the time had not yet come when they could be dogmatic as to the exact technique, but recent work suggested that the ideal to be aimed at was to distribute the radium as uniformly as possible throughout the growth and to expose the tissues for at least twenty-four hours, possibly much longer. He thought that as a palliative measure radium treatment had already more than justified itself, as a curative agent it was still too early to make any dogmatic statement. Mr Donaldson had observed that the vulva would not stand anything like the intensity of dosage with radium such as could be safely employed in the cervix or corpus uteri. He could not report favourably on a indication for inoperable carcinoma of the ovaries. Mr Donaldson hoped that at no very distant date centres for radiological treatment might be set up in different parts of the country. In the discussion which followed, Mr Tinsdale (London) described the technique he had adopted and the precautions that must be taken before radium was applied. Mr Strachan (Cardiff) referred to the risk of applying radium if promoters were present. He described the methods and results obtained so far at Cardiff. Miss Frances Ivens (Liverpool) referred to the excellent palliative results obtained by the use of radium emanations. A paper was then read by Dr D C Hue (London), embodying a preliminary investigation into the circulatory changes in normal pregnancy. Dr Hue described how she had noted the pulse rates of women at the different stages of their pregnancy, and how these were affected by change of position and exercise tests. She had also noted the blood pressures in each case. Her results on the whole showed that the condition of the cardio-vascular system in the pregnant woman compared very favourably with that of other women.

Friday, July 24th

OPERATION FOR BACKWARD DISPLACEMENT

The Section met on the final day to discuss the role of surgery in the treatment of backward displacement of the uterus. The opening paper was read by Miss Frances Ivens (Liverpool). Dr Ivens directed her remarks particularly to the group of cases which she described as the immobile, non-adherent, backward displacement, and she included in this group both retroversions and retroflexions. She wished to exclude cases of prolapse as outside the scope of her paper. She had stated in 1912 that one did not often find a definite retroversion which was not giving rise to symptoms, and she had not changed this opinion. She thought it would be useful if statistics could be collected with a view to ascertaining the frequency of congenital backward displacement. She combated the view that backward displacement in unmarried women caused no symptoms, or that if present these symptoms were due to neurosis. In a large number of cases remedy of the lesion caused the symptoms to disappear. A neurosthenic condition might be caused by displacement, and if the displacement were corrected in time the neurosthenia would clear up. It was difficult to trace strain as a cause, but it was a fact that this condition was more commonly met with in women leading a life involving hard and heavy work. In the acquired cases the commonest causes were pregnancy, fibromyoma, ovarian tumours, dorsal decubitus during a long illness or during the puerperium. Dr Ivens then described the pathological changes which occurred as the result of the displacement both in the

uterus itself and in adjacent structures. After outlining the principal signs and symptoms she cited a number of cases to illustrate the results obtained by operative treatment. Operation was rarely necessary when backward displacement occurred and was corrected early in pregnancy or the puerperium, and the presence of grave organic disease was a definite contraindication, otherwise she did not agree with trying pessary treatment first to see whether any improvement would result. The operation she favoured was Mayo's modification of Gilliam's method. She had operated upon more than a thousand cases, with five deaths. Of 200 cases subsequently traced, 68 per cent were cured of all symptoms, 14.5 per cent improved, and 15.5 per cent derived no permanent benefit. Her results had been rather better in single women than in married. Dr Russell Andrews (London), who followed, remarked that the uterus was frequently accused of being fixed in the backward position on insufficient grounds. It was very remarkable how practices differed in the types of cases seen. He very rarely saw a case of retroversion in a young girl which called for treatment. In many of Dr Ivens's cases other measures, such as emetting and dilatation, had been done in addition to fixation of the uterus. He agreed entirely that it was absurd to say that pain with retroversion was purely due to neurosis. He found it difficult to accept all the changes which, it had been said, might take place in the ovary. He also could not imagine a non-pregnant uterus causing retention of urine or pressure effects on the rectum. The only cases in which he advocated operation were those in which dyspareunia, severe backache associated with premenstrual pain and excessive bleeding, and abortions occurred. Dilatation and curetting was frequently all that was required. He had never come across a case of pyometra arising solely from this condition. Dr Andrews explained the technique of the operation he practised when he found it necessary to do an abdominal operation.

In the discussion which followed, Mr Parmore (Rugby) gave a brief history of the operative treatment of backward displacement, and referred to the role of intra-abdominal stitches and the importance of a well developed muscular abdominal wall in returning the viscera in position. Professor Swayne (Bristol) referred to the necessity of restoring the anatomical condition of the parts when operative measures were undertaken. Professor Marlow (Toronto) emphasized the importance of thorough repair of the pelvic floor. This was of greater importance than mere fixation of the uterus. Dr Farquhar Murray (Newcastle) spoke against operation being done except in very well defined cases. Dr Anderson (New Zealand) asked for information as to the operative measures most favoured in this country. Mr Leith Murray (Liverpool) only operated in cases of dyspareunia, sterility, or prolapse. Colonel Green-Armstrong (Calcutta) thought that there was far too much operating on the abdomen. In the East women only came for treatment for retroversion when it was complicated by either sterility, dyspareunia or prolapse. Mr Chisholm (Dundee) pleaded for the more frequent performance of the operation of interposition in women past child-bearing age. Miss Stallard (Hereford) claimed that exercises to strengthen the muscles of the abdomen and pelvic floor were far superior to any form of artificial support. Mr Rayner, Vice President (Bristol), closed the discussion, and Dr Ivens replied to her critics. Dr Strachan (Cardiff) then read a paper on the pathology and treatment of cervical erosion, which was followed by a brief discussion, in which Mr Parmore (Rugby) and another speaker took part.

SECTION OF PATHOLOGY AND BACTERIOLOGY

Thursday, July 23rd

PATHOLOGICAL BASIS OF TREATMENT BY RADIATION

The discussion was opened by Professor Sidney Russ, who pointed out that, in spite of the extreme antiquity of heliotherapy, little was known of its essential processes, and hence its pathological basis was not so well defined as was the case with x-rays and radium. Pathological researches had shown that cellular degeneration was a frequent sequel

to irradiation of tissues, the degeneration consisted in various abnormal features appearing among the cells at different times after irradiation. These changes might be due either to a direct action of the radiation upon the internal constituents of the cell, or to a direct action of the radiation upon the interface of the cell or to an indirect action which irradiation initiated. Various tissues responded differently to a dose of radiation ($Q \times t$) according to whether the time of exposure was short Q being large, or long Q being short. Izumi and Barlow found that in order to eliminate undesirable damage it was better to keep the quantity of radium low and prolong the time of irradiation when dealing with quiescent cells, while the reverse held good with dividing cells. It was still obscure why there should be a difference in the reaction of the tissues when the actual dose was constant, the only variation being in the conditions of exposure. Certainly during a long exposure more cells would come under irradiation in a state of division in which condition many cells were known to be more vulnerable than in the other stages of growth. Before accepting this basis of explanation they required proof that the intensity of radiation used was enough for a lethal dose to be given during the actual time taken for division, and that the period of radiation extended over a period equal, or nearly equal, to the time for the cell cycle.

Dr T S P Strangeways gave a description of the effect of irradiation by x rays on cells undergoing division in tissue cultures of the embryonic fox and on the embryo while in the unopened shell. The effects were observed during experiments which were being carried on by himself and his co-workers, Drs Canti, Donaldson, Hopwood, and Spear. These experiments indicated that even small doses had a pronounced inhibitory effect on cell division, and that it prevented new cells from coming into mitosis. Such small doses caused a definite retardation of the different phases of mitosis in those cells which had already begun to divide before the commencement of irradiation. It was found that there was no definite evidence that cells in actual mitosis were more vulnerable than those in a vegetative state. It was further found that within the limits of the experiments variation in the quality of the incident dose of x rays as measured by a Friedrich ionizationmeter had no appreciable influence on the dose required to prevent mitosis. Miss M E Hume read a paper on the action of ultra-violet light upon the growth of rats. She described experiment 11 work which proved that light cannot substitute cod-liver oil indefinitely for the growth and well-being of the rat. Although calcification might be promoted by the light, yet the set of symptoms due to injury to the mucous membrane eventually occurred. It seemed that some reserve was gradually used up. Possibly this other limiting factor was the original vitamin A, though how far this was completely independent of the light or antirachitic factor was unknown. Antirachitic properties had been given to various inactive substances by exposing them to ultra-violet radiation, and when fed to rats they produced the same effect as direct irradiation. Dr A Pincus declared that the effects of radiation on the bone marrow were essentially destructive in character, shown by nuclear degeneration of cells without disappearance of adipose tissue. In the lymphatic glands the results of radiation resembled those due to inanition, but occurred much more rapidly. X rays caused rapid and extreme involution of the thymus. The changes in the spleen were difficult to interpret because considerable variations occurred in response to different doses. In the blood most investigators had shown that there was a distinct reduction in the number of leucocytes, depending mainly upon decrease of neutrophils, with consequent relative lymphocytosis. The nature of the changes occurring in the blood was still a controversial question.

Dr R A Smith and F G Spear discussed the biological effects of radium irradiation on tissue cultures. The effects were undertaken as a result of certain observations on cases treated by Mr Malcolm Donaldson. Among these observations was the absence of the effects observed as soon as the radium was removed. Twenty-four hours *in situ*. The pre-

liminary observations on tissue cultures were purely qualitative. Tissue cells were examined in the thin section for prolonged periods under the microscope, and under the influence of radium. The following conclusions were reached. Cells in mitosis divided in vitro appeared to be normal in form and the daughter cells developed into fully developed apparently normal vegetative cells and did not pass into mitosis. For a certain period, the length of which depended on the intensity of irradiation, cells continued to come into mitosis without irradiation but at the end of this period no more cells came into mitosis. Being satisfied that radium irradiation brought about no definite change in the culture, quantitative experiments were undertaken with a view to determining whether the same amount of irradiated energy brought about the same biological effects irrespective of the time over which the energy was radiated—but if the radium was removed further from the tissue culture to a distance whereby the incident intensity was halved, then would double the time be required to produce the same biological effect. The physical measurement of intensity of irradiation at various distances were made by a photographic method, and curves were drawn up comparing the physical effects with the biological effects as determined by the time taken at various distances to cause cessation of mitosis. These curves showed that when the radium was near the tissue culture there was no observed departure from the physical readings, but that at a greater distance a long time was required to bring about the same effect than would be interpreted from pure physical laws. Further, the shape of the biological curve suggested that beyond a certain critical distance from the radium no biological effect might be expected. At this stage of the investigation this course of events could not necessarily be translated into conditions when radium is applied to eucromion in vivo.

Dr Helen MacLay and Dr H L Shaw read a paper on foodstuffs irradiated with ultra-violet light—their effect on the bone lesions of rachitic children. They showed that the effect of direct exposure to ultra-violet light on the bone lesions of a rachitic patient appeared to depend upon the power of light to produce in certain substances the so-called antirachitic factor. Dried milk irradiated with ultra-violet light from the mercury arc brought about rapid healing of the bone lesions in children, and thus antirachitic properties of the milk withstood ten minutes' boiling. It seemed probable that the action of a foodstuff artificially rendered antirachitic by irradiation with ultra-violet light was identical with the action of a naturally occurring foodstuff containing the antirachitic factor. When cod liver oil could not satisfactorily be given to a patient, then possibly an irradiated substance might in the future be of considerable value.

Friday, July 24th

PATHOLOGY IN RELATION TO RESEARCH

The third meeting of the Section of Pathology and Bacteriology was devoted to a discussion on the subject of the present position of pathology and bacteriology in this country, with special reference to research. Professor Ledingham, the President of the Section, opened the discussion. He referred to the statements made in the last annual report of the Medical Research Council, which suggested that whereas notable advances had been made during the last five years in other branches of medical science, notably physiology, yet little could be found to place to the credit of pathology. A general review of the work done by pathologists and bacteriologists did not in his opinion justify this generalization. No doubt pathology and bacteriology had suffered from an undue concentration in the purely practical and didactic aspects of these subjects, both in the matter of undergraduate teaching and in their application to practical medicine. Unlike physiology, which had remained largely aloof from practical medicine, pathology and bacteriology had given to practical medicine an unstinted and largely unrequited service which had entailed a considerable sacrifice of time and brain that might otherwise have been given to research. To return under university supervision the best features of routine diagnostic service, whether from hospitals or municipal health departments would demand a greater expenditure

for extra staff, equipment, and accommodation, but he declared it to be his conviction that the university association was worth preserving in some reconstructed form in the best interests of the existing race of pathologists and bacteriologists and of the particular health or hospital authority enjoying the university connexion. Dr Ledingham then went on to speak of the position of research institutes, and pointed out that experience showed that experimental pathology and bacteriology, comparative pathology, research in serum therapy and specific disease prevention, supplied under the conditions of the research institute a constant stream of problems the solution of which might or might not have their immediate echo in practical medicine. Undoubtedly it was a great advantage to have a research hospital attached to the institute. Research hospitals had been established in connexion with the Rockefeller Institute and the Pasteur Institute. The Lister Institute would follow their example if sufficient funds were at hand. Professor Stewart (Leeds) found himself in full agreement with the views expressed by Dr Ledingham. He spoke of the problem of training pathologists and discussed the qualifications a candidate for laboratory work should possess. Turning to the criticisms expressed in the last annual report of the Medical Research Council he said he did not agree, among other points with the wholesale ban on routine work therein pronounced. He emphasized the value of morbid anatomy, and referred to the invaluable and almost inexhaustible field for original research presented by the *post-mortem* material.

Professor Cul Browning (Glasgow) spoke on the training of research workers, and pointed to the advantage of a preliminary whole-time research fellowship. On the subject of facilities for research, he considered it to be not excessive if every member of the staff of every pathological department had at least half of his working time free to devote to research work. He deplored the neglect of the facilities which exist at fever hospitals for the study of infectious disease, and appealed for a closer association of research in animal and human pathology. He thought that endowments for research ought not to be limited to the investigation of some particular specified problem or disease. Dr Buxton Hicks (London) said one difficulty pathologists had in London was the inadequate accommodation for experimental animals in their laboratories. A pathologist was often expected to teach all day from 10 a.m. to 5 p.m. and do his research at night. Speaking of the training for research, he said that a research investigator must first be trained in ordinary routine work. He thought that pathologists ought not to be dependent on outside work for their support, but should be adequately paid by the universities or hospitals they served. Drs. Atkright, Okell, and Dukes took part in the subsequent discussion. In his reply, Dr Ledingham said he was sorry that Dr Buxton had not been able to contribute to the discussion. He remarked that the meeting appeared to be unanimous that certain grave abuses, whereby university chairs were supported by work done for outside bodies, should be removed. But he thought it inadvisable that some connexion should be maintained between university and public health authorities. There seemed no evidence to prove that routine work sterilized research, but a research worker must have leisure and often complete freedom from routine duties. He hoped that steps might be taken to bring the views of this Section of the British Medical Association to the notice of universities and hospitals throughout the country.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE

Wednesday, July 22nd

MULTIPLE NEURITIS

The first day's proceedings were devoted to an interesting discussion on the causation and symptomatology of multiple neuritis. Dr T. Grainger Stewart, in opening, said that he proposed to include under the term "multiple neuritis" all those cases in which, as the result of a general cause—toxic, infectious, or metabolic—the symptoms pointed to a more or less simultaneous affection of many of the peripheral nerves or of their associated neurones. He considered

that in the present state of our knowledge it was impracticable to classify "multiple neuritis" on any other than an etiological basis. From this standpoint he divided the cases into four main groups: (1) Exogenous poisons (lead, arsenic, alcohol, etc.), (2) endogenous toxins (metabolic—such as diabetes and beri-beri, cachectic and infective the latter including the infectious fevers), (3) multiple neuritis of obscure origin—the so-called rheumatic form, and (4) local infections of nerves (leprosy, interstitial hypertrophic neuritis, etc.). The two factors which determined the mode of onset and the distribution of the lesions in multiple neuritis were: (1) the selective action of the poison, and (2) the distribution of the poison within the nervous system. They knew that the nervous system had the property of fixing certain toxins—for example those of tubercle, diphtheria, and tetanus. Toxins and bacteria might enter the central nervous system either by way of the blood stream or by the perineural lymphatics. The speaker then proceeded to describe in detail the pathogenesis and symptoms of the different forms of multiple neuritis, and concluded by summarizing the features of the symptomatology of multiple neuritis as follows: (1) the spontaneous onset of the symptoms, (2) the evolution, in time and stages, of the clinical picture—(a) motor, (b) sensory, and (c) reflex—(3) the symmetrical and bilateral nature of the symptoms.

Dr Wilfred Harris (London) was commenting on Dr Grainger Stewart's classification, and said that he considered the third and fourth groups were unnecessary and that the forms included therein would fall in either the exogenous or endogenous toxin group. He disagreed with the speaker that lead neuritis was segmental in distribution, while in many forms of toxic polyneuritis sensory changes were absent. Dr W. Johnson (Liverpool) referred to certain atypical types of lead neuritis which appeared to flout the theory of the selective action of the toxin. But, he considered, might be a contributory factor in determining the site of the lesion. The speaker concluded by describing two interesting cases of acute infective polyneuritis under his care. Dr F. J. Nuttall (Newcastle-on-Tyne) referred to the hypertrophy and thickening of the peripheral nerves which sometimes occurred in multiple neuritis. He had examined such nerves microscopically usually with negative results, but one specimen had shown perineurial cell infiltration. Dr S. A. Kimber Wilson (London) considered the term "neuritis" was onerous in many cases of multiple neuritis, since changes occurred in the anterior horn cells and muscles as well as in the nerve trunks. It would be more correct to term such cases "neuronal" or "polyneuronal." He also mentioned the condition known as "central neuritis." Dr C. Weisberg-Drought (London) referred to the occurrence of myasthenia in multiple neuritis, especially the alcoholic form. He also described a case of recurrent multiple neuritis in which three recurrences had taken place in three years, each being ushered in with acute gastric symptoms. Dr A. T. Hurst (London) discussed the question of latent peripheral neuritis and considered that absent ankle-jerks were sometimes the only indication of alcoholism. Such cases should not be confused with tabes dorsalis, in which the reflexes were abolished whereas in alcoholic neuritis they were tend. Cirrhosis of the liver and neuritis appeared to be mutually exclusive; the alcoholic might develop one or the other, but never both. In the unavoidable absence of Dr J. S. Collier (London), his paper was read by Dr E. Mapother. Dr Collier considered it peculiarly fitting that Dr Grainger Stewart should open this discussion on multiple neuritis, for it was his father, Sir Thomas Grainger Stewart, who, forty-five years ago, wrote the first monograph on this subject in the English language. Dr Collier then described cases of alcoholic neuritis, with Korsakow's syndrome, in which he considered the cerebral neurone were involved.

The President Sir Maurice Craig, after congratulating Dr Grainger Stewart on his opening paper, said that in many cases of multiple neuritis mental symptoms were present and might even prelude the motor. He pleaded for an examination of the mental functions with just as much care as that with which the motor and sensory systems were investigated. Dr E. Mapother (London) said that in alcoholism, as with cirrhosis and neuritis in alcoholic psychosis and cirrhosis of the liver were seldom or never

found together Professor Edwin Binnwell (Edinburgh) considered that in many cases of multiple neuritis the cause was most obscure and could not be traced. He also referred to the occurrence of multiple neuritis and even Korsakow's syndrome in association with hyperemesis gravidarum.

Thursday, July 23rd

INSOMNIA

In this Section, on the second day, the proceedings were devoted to a discussion on the treatment of insomnia, which was opened by Dr. Robert Hutchison (London). The meeting was exceptionally well attended, and the observations of different speakers revealed considerable divergence of opinion as to the treatment of sleeplessness. For purposes of treatment Dr. Hutchison divided cases of insomnia into two groups: (1) the secondary, and (2) the primary. In the secondary group the insomnia was the result of physical discomfort, such as pain, dyspnoea, flatulence, etc., while the primary cases arose either from some physical discomfort (worry, anxiety, etc.), or were originally secondary cases, in which the physical cause having disappeared, the insomnia had persisted as a result of auto-suggestion. The treatment of secondary insomnia was primarily that of the associated disease. Dr. Hutchison thought it would be generally agreed that there was no objection to the use of hypnotics from fear of establishing a habit, as the disease was usually one of short duration, and sleep was essential for the maintenance of the patient's strength. In the dyspnoea of cardiac cases he thought there was no need to equal morphine, but in dyspnoea of pulmonary origin it was usually contraindicated. In such cases Dover's powder was often useful. For the sleeplessness of infancy, he considered that morphine was most effective, and that the common prejudice against its use in infant cases was unjustified. In apparent primary insomnia it was always as well to make sure that the case was not really one of secondary insomnia, as dyspepsia and constipation might cause sleeplessness. Although the patient was hardly aware of their existence. In primary insomnia the practitioner's first duty was to inquire into causes of mental discomfort (anxieties, etc.) and to try and persuade the patient to adopt the right mental attitude towards his symptom. Excepting in the rare cases in which insomnia resulted from overwork, he believed it better to attempt a cure in the environment in which it arose. Lastly, Dr. Hutchison dealt with the question of drugs, and stated that in his opinion the fear of establishing a "habit" was a bugbear. As one could not afford to fail without making the patient worse, it was wise to begin with a dose rather more powerful than really necessary. The hypnotics he favoured were bromial, radlin, and medural.

Dr. Harry Campbell (London) defined insomnia as the inability to enjoy a sufficiency of sleep under satisfactory conditions. In all cases it was essential to raise the level of the patient's general health. Dr. Henry Devine (Portsmouth) dealt with the difficult question of insomnia in the acute psychoses. Hydrotherapeutic measures were of great value. The aim should be to treat the condition responsible for the insomnia rather than the insomnia itself. Dr. C. P. Symonds (London) discussed the physiological mechanism of sleep, and mentioned the different ways in which it might be disturbed. Dr. L. I. Spriggs (Ruthin Castle) mentioned the importance of a certain daily allowance of flesh and also described how the reading for a definite time of prescribed literature might assist the onset of sleep. Dr. Stone (Northampton), speaking from thirty years' experience of general practice, laid great stress upon the presence of a certain amount of food in the stomach, and also the patient's posture. Dr. W. Johnson Smyth (Bournemouth) referred to his experiences with hyosine in asylum practice. He had found medural the best all-round hypnotic. Dr. W. A. Potts (Birmingham) drew attention to the value of combining hyosine with morphine in ecstacy cases, while simple drugs, such as "blue pill" and alcohol, were often useful. Dr. Moritlock-Brown (Braunton) pleaded for further research into the physiology of sleep, and deprecated the use of hypnotics. Dr. McKenzie Wallis (London), in dealing with the question

of the relative toxicity of hypnotics, stated that experimentally he had found that sulphonal, veronal, and medural had no effect on the liver, kidneys, or general metabolism. The discussion was terminated by the President, Sir Murray Craig, who stated very emphatically that experience had taught him to treat sleeplessness in its earliest stage, even in children, and that he had no fear of the use of hypnotic.

Friday, July 24th

PREVENTION OF MENTAL DISORDER

On the third day in this Section the President of the Royal College of Physicians, Sir Humphry Rolleston, opened a discussion on the prophylaxis of mental disorder. Although in a special Section, Sir Humphry considered that a discussion should be on very broad lines, as it dealt with the highest reactions of the human organism, in fact with its reaction as a whole whereas in other branches of medicine one organ or system of organs chiefly attracted their attention. It was right that the discussion should be opened on general grounds, and it would have an educational value for those interested in general medicine rather than in psychological medicine. The public, as well as the medical man, required education as to the manner in which mental abnormalities should be regarded and should be impressed with the similarity of mental and bodily disorders, and with the commonplace that prevention was better than cure. A regard to etiology, the multiplicity of causes of mental disorder—heredity, environment, physical or bodily, and purely psychological—complicated the problem of prevention. Heredity and environment were closely interwoven as etiological factors. The special form of nervous disorder was not indicated as such, and a low state of vitality was handed down. Environmental conditions could be improved by all that was included under the term "mental hygiene." Half the cases of mental disorder had been ascribed to the influence of heredity. This factor carried with it as means of prevention the difficult subject of eugenics, sterilization of defectives, and birth control. Care was necessary, however, as if eugenics were carried to their logical conclusion a dead level of standardized men might result. Sir Humphry Rolleston then proceeded to deal with the various forms of stress—physical and psychical—which might act as the exciting factor on a psychopathic disposition. Among these were trauma, infection, toxic factors, unsuitable diet, worry, emotional strain, and overwork. Chronic infective foci appeared to play an important part in some cases of mental disorder. It was reported that at the New Jersey State Hospital, Trenton, the discharges increased from 37 to 85 per cent after removal of oral and tonsillar infections. The effects of alcoholism and syphilis were well recognized. Endocrine deficiency was an interesting and possible responsibility. When of congenital origin (for example, cretinism) ante-natal treatment and environmental precautions might be helpful. Educational dangers at school—the overpressure often brought to bear on clever boys—the importance of sufficient sleep, and finally early treatment in psychiatric clinics attached to general hospitals, were further factors presented by the opener in his admirable paper.

Dr. Helen Boyle (Hove) pointed out that, as regards eugenics, there was no definite model at which to aim. Physical perfection did not necessarily mean good mental development. She also dealt with the correct upbringing of children. Dr. Bernard Hart (London) maintained that there were no disease entities in mental disorder—that what occurred was a reaction of the whole organism to its internal and external stresses. While they clung to the disease entity idea it was difficult to harmonize the different etiological factors. He pleaded for more tolerance between the various schools of psychological thought. Dr. L. Mapother (London) deplored their lack of information as to prophylaxis. They needed some test of susceptibility to mental disorder—a test analogous to the Schick test in diphtheria. Dr. T. A. Ross (Penshurst) said that the medical student was not taught to interest himself in mental disorder, very few general hospitals had psychiatric clinics, and the majority of psycho-neurotics were allowed to drift owing to lack of suitable treatment. It was the general practitioner who should really be in a position to help these patients. Dr. W. A.

Potts (Birmingham) considered that the places for the prevention of mental disorder were the ante-natal clinic and the nursery. Dr P. Watson-Williams (Bristol) dealt with the importance of the removal of chronic infective foci in the teeth, tonsils, or accessory nasal sinuses. Dr H. Crichton-Miller supported him, and added observations on the blood examinations of psycho-neurotics. Dr R. M. Craig described the psychiatric clinic attached to a general hospital with which he was associated, and Dr Davidson, Montpelier-Brown, and Madgson also spoke. The discussion was then brought to a close by the President (Sir Maurice Craig), who added a further plea for the establishment of psychiatric clinics in connexion with all general hospitals, and also for recognition of the importance of avoiding overstimulation and fatigue.

SECTION OF THERAPEUTICS (INCLUDING BALNEOLOGY AND RADIOTHERAPY)

Wednesday, July 22nd

ASTHMA

In opening the discussion on asthma, the President, Professor R. B. Wild, reminded the audience how modern many of their methods of treatment were. He had read his first paper before the Section in 1887, when Professor Lieberich, the discoverer of chloral-hydrate, had also spoken. He congratulated the Section on meeting in the historic city of Bath, where so much was done for the science of therapeutics. The results of organized research begun in 1911 with the establishment of the Medical Research Committee (now Council), were now being reaped. It was time to take stock of their knowledge.

Dr W. Langdon Brown (London), in opening the discussion, said that the treatment of asthma summarized in itself the chief trends of modern therapy. Successful treatment involved a consideration of psychotherapy, sensitivity to foreign proteins, vagotonia, and endocrine balance. Asthma was due to an unstable or irritable condition of the bronchomotor or vasomotor portions of the vagus nucleus which then reacted unduly to psychical or peripheral stimuli or to foreign proteins in the blood. Immunity to certain foreign proteins was congenital, there were others to which immunity might be required. But to some foreign proteins immunity was never required and they could not be assimilated. Such proteins exerted anaphylaxis in varying degrees. The asthmatic showed a sensitiveness towards proteins which were not toxic to others. As a rule they had difficulty in dealing with a number of foreign proteins. They would give a strongly positive reaction to one at one time and to another at another time. Only occasionally was there a high degree of sensitiveness to a particular one. For this reason the skin test was reliable in only a small number (2 to 3 per cent) of cases. Asthma depended largely on an upset in the balance between the parasympathetic and sympathetic branches of the visceral nervous system. Asthmatics were vagotones. The vagus preponderance might be relative and due to depression of the sympathetic, or to drugs or any condition exerting the sympathetic relief of asthma. In summarizing the treatment of asthma the speaker recommended an all-round attack on the disease. He would consider the psychical aspects of the case, remove sources of peripheral irritation, employ exercises for chest development, desensitize where practicable, restore the balance in favour of the sympathetic, or attend to the general hygiene.

Dr F. P. Poulton said that it was important to distinguish between idiopathic asthma from that due to infection. It seemed also certain that cardiac asthma in the elderly was not true asthma. Patients of this type were benefited by morphine or oxygen inhalation. Skin reactions were of no value for the diagnosis of particular substances, but they served to distinguish between cases of the allergic and infective groups. For this purpose he used an extract of human dander injected intracutaneously. Asthma was not due to anaphylaxis any more than histamine shock was due to anaphylaxis. Allergic individuals were often sensitive to drugs such as aspirin. Treatment should be directed to the allergic condition, and might be specific or non-specific, as by injections of milk or peptone, to keeping the patient away from the specific exciting substance to

altering the receiving mucous membrane, as by touching certain points with the ear, or to relaxing the bronchial muscle, as by injection of adrenaline, of caffeine or by oxygen inhalations.

Dr Philip Hamill emphasized the importance of history in eliciting a substance to which the patient was sensitive. Six reactions had a certain value, but there were practical difficulties in carrying out a complete series of tests. If a specific precipitating factor could be determined—for example, horse, feathers, etc.—(1) remove or avoid it, (2) immunize against it either specifically by injection of minute doses, or non-specifically by peptone. Chronic bronchitis, so often associated with asthma, made the patient more sensitive, it was therefore important to treat the bronchitis. Vaccine therapy was a valuable adjunct. Dusty regions and occupations should be avoided. During an attack adrenaline was of great value if given early, and pituitary extracts assisted. Between attacks every endeavour should be made to build up the strength and resistance of the patient, undoubtedly attacks were much less liable to occur when the general condition of the patient was good.

Dr Alexander Roberts said that the chief aim in the treatment of asthma was to stabilize the vasomotor system. The problem of asthma would be found in the vagus and sympathetic nerves and their effects on the circulation. He was supposed to advocate indiscriminate cauterization of the nose, but much damage might be done by excessive cauterizing. He gently touched certain spots on the mucosa while watching the effects of treatment on the blood pressure. Ordinarily cases responded well, but when nasal polyps were present the use of the cautery was contraindicated, and the cases were much more difficult to treat. Dr A. F. Hurst said he had himself suffered with asthma for thirty years. The condition might be alleviated, in favourable circumstances the attacks might even cease, but there was no cure. An asthmatic was always liable to recurrence of attacks. The best treatment was avoidance of fatigue and sufficient holidays in places where the attacks did not occur. Mr Frank Cole classified the types of asthma. He believed strongly in the importance of skin tests. If the offending protein could not be avoided desensitization should be tried and was often extremely successful. He also recommended auto-hemotherapy. Dr Baker described an apparatus for administering adrenalin in oxygen gas. Dr Birch said he had been incapacitated for two years by asthmatic attacks, but was now cured, thanks to Mr Coke's method. The President spoke of the relation between asthma and eczema.

Thursday, July 23rd

TREATMENT OF CHRONIC ARTHRITIS

A discussion on the treatment of chronic arthritis was opened by Sir Thomas Horde. He said that drainage or other appropriate treatment of the area of focal infection was the first step in treatment. If teeth and tonsils or teeth and gastro-intestinal tract were both involved the teeth should receive thorough attention, and an interval be allowed before drastic measures were employed with regard to the tonsils or the bowel. So with the throat and nose on the one hand and the rest of the respiratory tract on the other. Antigen therapy should be supplementary to drainage of the infected area, not a substitute for it. In the great majority of cases chronic arthritis was part of a general disease, and the patient required treatment as much as, and sometimes more than, the joints. He discussed the various forms of treatment, general and local, and concluded with some remarks on the treatment of chronic arthritis by protein shock. Dr Preston King (Bath) discussed the hydrotherapeutic treatment of this condition. He believed that the thermal waters, in the external and internal use, were to be regarded as one of the constituents of the pharmacopoeia, and, like any other remedy, had then proper use in appropriate cases. In treating chronic arthritis by hydrotherapeutic methods, it was results, not causes, which were being treated, and although the later stages of disorganized joints with eroded cartilage, irregular bone formation and fibrosis, or even bone ankylosis, came up for cure, it was obvious that no

benefit, beyond perhaps some alleviation of pain, was possible. He described the treatment followed at Bath, and stressed the advantages of a spa where a thorough course of baths could be taken together with electrical and heat treatment and massage. Dr. A. Mutch (Guy's Hospital) approached the subject from the bacteriological point of view, and mentioned some work which he had carried out on cases of chronic arthritis due to *B. foliaceus*, a little known microbe studied in the past chiefly in connexion with war wounds. In certain insidious cases it had appeared to be the primary bacteriological factor, but it probably played an equally important part as secondary invader, keeping up residual inflammation in joints thereby damaged by infective cocci. Dr. C. B. Heald described certain types of this condition which were recognized when special examinations for pilots were instituted when there were a cardio-vascular debility type, a nervous instability type, and a malnutrition type. As a further guide to the selection of treatment he had formulated for himself certain rough working rules, as for example that there was, not seldom, some deformity due to the causative disease to be found from the actual joints affected, or from the order in which they became affected, and that the less a joint was free to move the less was electrical treatment likely to be effective unless this could be directed to some central focus or unless the focus had already been discovered and received adequate treatment. He went on to discuss the treatment of chronic arthritis from the electrotherapeutic point of view. Dr. J. P. Chamberlitch explained the advantages of diathermy, which he thought could be regarded as a specific for gonococcal arthritis, and in some cases of rheumatoid arthritis with no evidence of gonococcal infection diathermy had apparently cured the condition. Dr. Warren Crowe thought that in arthritis and non-articular rheumatism—which might be classed together—vacuums ought to do well, yet in practice the bilmer of opinion was unfavorable to this method of treatment. This was partly the fault of bacterial technique but not mainly so. The chief fault was with the clinician, whose technique of administration was wrong. Dr. P. Watson Williams stressed the importance of excluding sources of infection in the upper air tracts. He also reminded upon the frequency with which neurasthenic symptoms were associated with rheumatoid arthritis cases, and there was no manner of doubt that the neurasthenic syndrome in these cases was due to the focal infection. Dr. David Campbell deplored rigid splinting, from the beginning the patient should be encouraged to move the affected joint, if this were done many disastrous sequelae would be prevented or minimized. The President of the Section (Professor Wild) remarked upon the way in which sufferers from this condition experienced an exacerbation just before the advent of damp weather. He attributed this to the accumulation of carbonic acid in the body. Dr. P. Hannell confessed himself unopinioned as to the use of splints in moderation, though he agreed that exercise and massage were important. Dr. Thomson was of opinion that if the general condition of these cases was poor they should be sent to a spa, if the general condition was good the most valuable thing for practical purposes was intravenous shock. Sir Thomas Horder, replying on the discussion, said that he had no intention of depriving the bacteriologist in some remarks he had made earlier, he was only anxious to 'ginger' the bacteriologist so that he might afford more reliable help. Nor did he wish it to be understood that he advised protein shock for the patient who was improving by any other method. The discussion had strengthened his main thesis, which was that arthritis was a general disease with local manifestations.

Friday, July 24th

THERAPEUTICS OR LIGHT

A discussion on the therapeutic value of light was opened by Professor W. E. Dixon, F.R.S., who said that besides the local and general action of light, in which it did not differ from the action of other agents, there was a specific action peculiar to light itself. This was shown by the capacity of light to alter the percentage of carotene and phosphorus in the tissues. However much calcium or

potash was taken by the mouth the percentage of the salt in the body could no more be altered than the gravity of the blood could be changed by drinking tea, but light was able to produce this effect, and consequently could prevent and cure rickets. The action was by way of a chemical change of the cholesterin in food or in the skin. It was not connected with the no-tolerance mind, it was simply a chemical change, which could be produced equally in the test tube. Dr. C. L. M. Jones (Alton) said that the two conditions in which light treatment had proved most beneficial were rickets and pulmonary tuberculosis. A very important indication in treatment was the capacity of the individual to absorb pigment. A patient who had a higher resistance to diseases than a non-pigmented one. His psychological condition of light was also worthy of study. Let us turn next to physically defective children in London schools, treated with children at Alton of the same age and suffering from the same condition showed the latter to be approximately one year ahead in mental activity as compared to the exposure at Alton to sunlight and air. With regard to artificial light sources, he preferred the carbon arc for general treatment and the mercury vapour lamp for local treatment. The tungsten arc is very useful in small glands of the neck. Contraindications for light treatment were non-pigmentation, feeble conditions, neuritic disease, and in very young and very old patients. Dr. G. H. Francis described the technique and results of phototherapy at the Skin Hospital in Manchester. Here the artificial sunlight treatment had been reserved for tuberculous skin cases, mostly lupus vulgaris and the results had exceeded expectations. He had used the tungsten arc mainly in the treatment of alopecia. In recent publications many skin complaints were stated to be curable by phototherapy. He trusted that a good cure would not be spoiled by too wide a claim. He was inclined on theoretical grounds to doubt the efficacy of local phototherapy on the deeper-seated psoriasis and skin affection. Although the value of phototherapy, local and general, was abundantly proved for tuberculous skin disease, more experience was required to establish its real worth in other departments of dermatology. Dr. W. Mitchell (Bridford) said that tuberculous glands responded well to light treatment, though this treatment was useless if an abscess was present. In cases of lupus a preliminary drainage of filtered air was a great help. Professor Hofferma referred to the incidence of endemic gonorrhea among populations in narrow mountain valleys, where the horizon was limited and a great deal of direct sunlight factors to account for the difference between the action of light on pigmenters and non-pigmenters might be racial type. The Mediterranean type understood the risk of tuberculosis much better than the purely Nordic type. Dr. E. P. Chamberlitch suggested that there might be advantages in using carbon arcs which had been impregnated with various metallic salts. Dr. Helen Mackay had found the dose was cut down with some children's sleep until dismissed posture in bronchial drainage. In order to diminish position that the bifurcation of the trachea was lower than both the bronchi, and this result might be obtained in three practicable positions which he described in detail, and indicated modifications which were useful with a view to efficiency and comfort should drainage be required frequently or over a long period.

SECTION OF LARYNGOLOGY, OTOTOLOGY, AND RHINOLOGY

Wednesday, July 22nd

The proceedings of the Section opened on the first morning when Mr. Arthur H. Cheate, the President, welcomed the visitors. Professor Cheate, Professor Thomas McCre, and Dr. Tucker of Philadelphia, Professor Burger of Amsterdam, Professor Birkett of Montreal and Dr. J.

Stoddart Barr of Tasmania Professor Chevalier Jackson opened a discussion on overlooked cases of foreign body in the air and food passages, and for two hours captivated a crowded meeting of over two hundred members with a brilliant summary of the subject, lavishly illustrated with lantern slides. Professor Jackson first emphasized the importance of the overlooked foreign body, its seriousness varied, for while some foreign bodies might remain for long in the lung without giving trouble, others foreign bodies might prove fatal in from one to three weeks in a young child. Foreign bodies were not irritating unless they were obstructive, and provided there was no obstruction they might be tolerated by the tissues for a long time. In discussing the causes of overlooking the foreign body, Professor Jackson said that one of the commonest was that the history of the foreign body was excluded. It was very important that teachers of medicine should impress their students that, in every acute or chronic case of pulmonary disease, foreign body must be considered. The attitude of the general practitioner and the general physician was often apathetic, and a definite history of foreign body given by the patient was frequently ignored or even ridiculed. Close cross-questioning would often elicit a history of foreign body which might otherwise be overlooked. The fact that a child was known to have been sitting on the floor (where children often picked up fruit stones and other small objects), and had had an attack of coughing and choking, was an initial symptom of the first importance, such a child should be deemed to have a foreign body until proved guiltless. If symptoms promptly followed the swallowing of a foreign body they would not be so often overlooked. Foreign body often simulated a symptomless interval. Foreign body often simulated common diseases, such as tuberculosis, emphysema, pneumonia, asthma, and diphtheria, but a careful examination should exclude these diseases. X rays were the most valuable means of diagnosis, but careful examination of physical signs should always be made by an expert. The lungs should be x-rayed both before and after the extraction of the foreign body, as sometimes there was more than one present. Professor Thomas McCrue regarded it as necessary that there should be team work—a radiologist and a bronchoscopist as well as the physician. He emphasized the importance of education, which was needed chiefly by the general practitioner and the physician, and he said that they had a right to demand increased skill and technique on the part of the bronchoscopist. In the ensuing discussion there took part Sir StClair Thomson, Sir William Milligan (Manchester), Dr Tucker (Philadelphia), Dr William Hill, Dr Irwin Moore Mr Herbert Tilley, Mr E B Waggett, Mr D A Crow (Brighton), Mr G Lwart Martin (Edinburgh), who emphasized the importance of having the intubation laws modified, so that the passing of bronchoscopic tubes could be practised on dogs anesthetized by morphine only, as in America, Mr Musgrave Woodman (Birmingham), Sir James Dundas Grant and Dr P Watson-Williams (Bristol). Professor Chevalier Jackson thereafter gave a practical demonstration on the manikin of mechanical problems of the bronchoscopy and oesophagoscopy extraction of foreign bodies from the air and food passages. He followed this with a cinematographic demonstration of bronchoscopic aspiration for suppurative diseases of the lung of other than foreign body origin. It was interesting to see boys jump on to the operating table, he down live the bronchoscope passed without any anaesthetic, and sit up again smiling.

Thursday, July 23rd

On the morning of the second day Mr G J Jenkins opened a discussion, before over eighty members on the operative treatment of chronic middle ear suppuration. He said that in recent years otologists in all parts of the world had been experimenting with methods that were something between the Schwartze and the radical mastoid operations, and which were termed conservative mastoid or modified radical mastoid operations. This endeavor to find something better than the latter had been found to be

insufficient or defective in some respects. Whatever the operation done, its objects should be to remove all foci of potential danger, to return the maximum hearing, and to leave a state of affairs that would necessitate the least possible after-attention. He had been led to employ an extended Schwartze operation, with removal of the middle ear, and to obliterate the antrum and mastoid cavity by means of a flap of periosteum, in cases of chronic otorrhoea in which he believed the disease was confined to the antrum, middle ear, and middle ear. The discussion was continued by Mr Sydney Scott, Mr J Bowring Horgan (Cork), Mr Aldington Gibb (Maidstone), Sir James Dundas-Grant, Mr W S Syme (Glasgow), and Mr Norman Barnett (Bath).

The next discussion, on the same morning, was on the treatment of chronic non-suppurative middle-ear deafness, and was opened by Sir William Milligan, who said that as his experience went, advanced chronic catarrhal otitis media was an incurable disease, and one in which all that could be done in their present state of knowledge was to endeavor to stem its progress and to prepare the patient for the advent of a severe degree of loss of hearing. The sheet-anchor of treatment was unquestionably inflation by means of either the bag or the Eustachian catheter. The existence of a genuinely stenosed Eustachian tube called for a preliminary course of bougienage, and to be effective this should be done through the tympanic membrane after a preliminary priacntesis, and preferably under a general anaesthetic. The presence of creeping sepsis was the underlying factor in the establishment of chronicity, and all obstructive or septic lesions in the throat, nose, and naso-pharynx should be carefully excluded. The education of the auditory centres should be systematized, and, if possible, simplified. In the somewhat unexpected optimistic discussion which followed there took part Dr J Kerr Love (Glasgow), Mr Neil Melny (Newcastle-on-Tyne), Mr Norman Barnett (Bath), Dr George Cathcart, Sir James Dundas Grant, Dr W S Syme (Glasgow), Mr Herbert Tilley, Mr Arthur Cheate, Professor Burger (Amsterdam) and Mr Sydney Scott.

Friday, July 24th

On the morning of the third day of the proceedings Mr F H Westmacott opened a discussion on occupational diseases of the ear, nose, and throat. He first discussed the occupational diseases which were scheduled under the Workmen's Compensation Acts, though in the majority of cases the disease or injury was not limited to the ear, nose, or throat but affected in even a wider degree the skin surface of the body, or the lungs or other organs, and the incapacity in most cases was not produced by the local affection but by its wider extent. These diseases included anthrax, lead poisoning and its sequelae, and mercury poisoning by nitrous fumes or its sequelae, ulceration of the mucous membrane of the nose or mouth produced by dust, chronic ulceration or its sequelae, compression of the ear included inflammation of the middle ear, inflammation and necrosis of the middle ear followed by rupture of the tympanic membrane in mining workers and blinding, etc. The deafness attributed to continuous noises due not so much to damage of the sound conducting mechanism as to destruction of the sensitive nerve ending which constituted the sound-receiving apparatus. The discussion was continued by Surgeon Commander J. Grimwade, R.N. (representing the Royal Navy), Wing Commander D Ranken, R.A.F.M.S. (representing the Royal Air Force), Major T Jefferson Gaulder, R.A.M.C. T.F. (who spoke on the subject as it affected the soldier), Mr T Ritchie Rodger (Hull), Mr E B Waggett Dr J Keir Love (Glasgow), Mr T B Johnson (Guildford), Mr H Norman Barnett (Bath), and others.

DEMONSTRATIONS

On the afternoon of each day demonstrations were given at the Bath Bar, Nose, and Throat Hospital. Mr V I Negus read a paper there on evolutionary factors in the causation of pharyngeal diverticula, illustrated by specimens and lantern views, and showed specimens illustrating the comparative anatomy of the nose and throat. Mr Irwin Moore read a paper on the history of endoscopy and demonstrated a number of specimens from the special endoscopic museum, for the formation of which he had made himself responsible, and which was one of the most striking features of the Pathological Museum of the Annual Meeting. Mr G J Jenkins exhibited specimens showing destruction of the tonsils as mentioned in his paper. Mr H Norman Brunett demonstrated a large number of cases illustrative of the excellent results he had obtained in the conservative method of operative treatment of chronic middle ear suppuration, and of the treatment of chronic non-suppurative middle ear deafness. Dr P Watson-Williams, assisted by Mr Eric Watson Williams, gave a demonstration, on patients under local and general anaesthesia, of his method of investigation of the nasal accessory sinuses.

SECTIONS OF DISEASES OF CHILDREN AND PUBLIC MEDICINE

Wednesday, July 22nd

PREVENTION OF RHEUMATIC INFECTION

Dr ROBERT HUTCHINSON presided over a joint meeting of these two Sections held to discuss rheumatic infection in childhood, its early diagnosis and preventive treatment. The opening paper was read by Dr T J Poynton, who first emphasized the importance of such infections, especially in its bearing on heart disease, as a cause of suffering and early death. All who were familiar with such cases were impressed by the recuperative power of the heart in early life, if it were rested and protected. The prevalence of chorea among school children, he thought, suggested some discoverable factor that was straining their nervous system. He hoped that by more careful organization and supervision they might prevent much of the harm that this disease was causing. With regard to prevention, it was wise to deal first with cases which promised a good chance of useful recovery, rather than those which were seriously damaged. Dr Poynton then gave a brief summary of the work recently carried out at the Hutfeld Hospital in Sussex, established by the Invalid Children's Aid Association. There, out of 123 rheumatic children admitted, only two at the end of a year, and after a period of much cold and rain, developed fever and rheumatic pains. During the same period in London he was seeing numerous cases of active rheumatism, some with general pericarditis. He was often asked if these measures would prevent relapses in the future, but could only say that by giving time to consolidate the heart and allowing Nature to build up the resistance of the tissues they would certainly help to repel future attacks. The ideal hospital for this purpose would have to be specially provided, and the problem confronting them in this matter was the question whether the public would be justified in spending the necessary funds. Dealing with the chief manifestations of rheumatism in childhood, he said that in 1108 cases 673 showed endocarditis, 626 arthritis, 617 chorea, 344 sore throat, and 94 had nodules. The earliest evidence lesion was usually dilatation. He was largely responsible, with Dr Price, for establishing the theory of a local focus of infection, and in this connexion was convinced of the importance of the emulcation of infected tonsils as a prophylactic measure in spite of exceptions. In regard to treatment he deprecated the routine use of salicylates. Their value in adult arthritis and for relief of pain he did not dispute, but for evidence cases in children he preferred the ethyl ester of para methyl cinchonic acid.

Dr R A Askins described some of the work that had recently been done in this connexion by the School Medical Department of Bristol. Accurate statistics as to the extent of the evil were not available, but, assuming that half the fatal cases of heart disease in the country were rheumatic in origin, they were losing over 18,000 lives a year from this

can. The disease was undoubtedly due to micro-organisms of the streptococcus group, but its incidence could be reduced if it was probably communicated by means of and prolonged infection. The school medical department gave the best opportunity for early diagnosis, and he advocated the establishment of special cardiac clinics and the utilization for these patients of beds in existing cripple hospitals. Dr Carey Coombs (Bristol) emphasized the necessity of collaboration between the clinician and the administrator. He hoped that future research would provide them with biochemical or other reactions which would facilitate early diagnosis. Any hospital for this purpose must provide open air and occupation. Dr R Miller mentioned the work which had been done by the Committee of the Association appointed as a result of the discussion at the Portsmouth Meeting. Its report would soon be issued, and he believed it would prove a very valuable document. Early cases of rheumatic infection were often mistaken for tuberculosis and the presence of pallor, dyspnoea, fatigue, with enlarged tonsils and a cough should always lead to a suspicion of rheumatism. The nervous and unstable condition of such children was a sign of nervous instability which had not developed into chorea. He thought the condition was associated with poverty and mentioned that at least situated as it was in the Thames Valley, there had been no case of the kind ever in a period of years. Dr Glover of the Ministry of Health thought the most important preventive measures were town planning, concreting of foundations to prevent dampness, and the avoidance of over-crowding in both homes and schools. He would like to see acute rheumatism made notifiable in certain areas for a period of years, and a completely equipped unit for the investigation and treatment of cases. Dr Vincent Court pointed out the frequency with which nodules could be detected in these cases, and then extreme importance in early diagnosis, enabling the physician to anticipate cardiac mischief. Dr R L Thomas did not regard rheumatism as a disease of poverty, but thought it affected rather the children of the better skilled artisan class—people who were succeeding in life but living under conditions of extreme strain. Dr Thompson called attention to the value of detection of hindwings as an early sign of the disease. In Birmingham they found that cases followed closely the course of the two streams which flowed through the city. He thought the establishment of special clinics would be very mischievous. These cases required not the cardiologist but the experienced general physician. Dr Nay Scott said that in rural districts where children had to walk long distances in all weathers to get to school, compulsory school attendance was a potent factor in causing rheumatism. Dr Justice Hill, Dr Price, Professor Wynne, Dr Leonard Tees, and Dr Semfield also took part in the discussion.

The Chairman, Dr Robert Hutchinson, said if it were not for the prevalence of rheumatism they could close at least fifty beds in the London Hospital alone. He also distinguished the provision of special clinics. He had learned to distrust the expert, especially the tuberculosis expert. Much more knowledge was needed before they could recommend the expenditure of large sums of money at a time when the country was already impoverished. With regard to the relation of the disease to poverty, his experience was that it was not a slum disease but a disease of elementary school children. Mental strain was an important factor in the development of chorea.

SECTION OF DISEASES OF CHILDREN

Thursday, July 23rd

TREATMENT OF EMPYEMA

The second day's discussion with Dr Carey Coombs in the chair was on the treatment of empyema. Dr H C Cameron said that the mortality from empyema was very high in the first two years of life. It was always a favourable feature when the rise of temperature due to the pneumonia was separated from that due to empyema by an interval of time (metapneumonic empyema). Conversely, the prognosis was unfavourable when pyrexia due to empyema was superimposed on that due to pneumonia (sympneumonic empyema). The latter was the prevailing type in pneumonias of infants, because at that age pneumonias tended to be of long duration. After the second

veal metapneumonic empyema was the rule and the prognosis was much better. An exception was influenzal empyema, which was generally suppurative. The treatment of the two forms of empyema was different. Cases of metapneumonic empyema recovered after rib resection, suppurative cases almost always died. In suppurative empyema paracentesis should be practised as a temporary measure, followed by rib resection at the termination of the pneumonia. Besides saving life, restoration of the function of the lung must be considered. Failure of the cavity to close was due to delay in the establishment of satisfactory drainage, insufficient drainage, and secondary infection. Mr H S Souttar said that the incidence of pneumonia was greatest between the ages of 1 and 7, and the mortality was highest in the earlier years. The mode of onset of the disease had a vital bearing on the mortality and method of treatment. The outlook was bad when empyema occurred as part of a general infection, or where the whole cavity was suddenly involved, as in a violent streptococcal infection. Immediate operation was apt to be fatal in these cases. When, however, the empyema was due to extension from subsidiary pneumonia the prognosis was good and radical treatment was indicated. From the point of view of operation empyemas fell into two groups—the adherent and the non-adherent. The former were usually pneumococcal, the latter streptococcal. In the first the speaker advocated opening the cavity freely, clearing out all solid masses of fibrin, and draining by a closed method, in the second to open the pleural cavity freely was to invite disaster. Pressure must be relieved by repeated aspiration. Later operation might be attempted. Closed drainage was preferable to open drainage for many reasons. Primary closure after emptying the cavity had proved disappointing. Post-operative treatment was as important as the operation. Its aim was sterilization of the cavity and expansion of the lung. The speaker recommended siphon drainage and in some cases injection of Dakin's fluid. With due care chronic empyema should never result.

Dr F G Chandler classified types of empyema into ordinary empyema following pneumonia, acute fulminating, chronic, or tuberculous empyema. In treatment four things had to be kept in mind—the evacuation of the pus, the expansion of the lung, the speediest convalescence, and the comfort of the patient. Rib resection in young children was unjustifiable, aspiration or simple incision and drainage gave better results. If the lung did not expand it meant either disease within the organ or thickened pleura and adhesions. The latter could be dealt with mechanically or by irrigation with Dakin's solution. Fulminating empyema should be treated by gentle aspiration, if necessary with an replacement to prevent too sudden emptying of the cavity. Mr W H C Romanis laid stress on the complications of empyema, such as sinus formation, fibrosis of lung, and bronchiectasis. It was important to identify the infecting organism. Pneumococcal infection was associated with masses of fibrin in the pleural cavity which often altered the physical signs. In pneumococcal empyema operation was not urgent. Young children might be cured by aspiration alone. In the streptococcal form the pus must be removed without delay. Aspiration should not be persisted in if the child did not improve in a day or two, but recourse should be had to operation. Mr T Twinstington Higgins said that the treatment of empyema must be guided by ordinary surgical principles. The important points were early and accurate diagnosis and efficient operative and post-operative treatment. The operative procedure would depend on the age and condition of the child, the character of the pus, and the size of the empyema. In his experience a knowledge of the bacteriology of the pus was not of much assistance in treatment. He advocated suction drainage and in suitable cases the aspiration method of Poynton and Reynolds. Dr Clarke gave his experience of primary closure of empyema. Out of twenty-one cases primary union occurred in two. In the others the wound broke down and a tube had to be inserted, but all did well. Dr L A Parris (Brighton) agreed with previous speakers on the main points. He thought primary suture hardly worth attempting. Rib resection was necessary in all cases to secure good drainage. Dr R A Ramsay pointed out that the cavity in empyema was often obliterated by the rising of the

diaphragm and the falling in of the chest wall after the pus had been evacuated. For this reason high incision and drainage were necessary. Dr J Willie Scott discussed the difficulties met with in dealing with very chronic cases of empyema. Mr Crymble (Belfast) agreed with Mr Ramsay that high drainage was necessary in many cases. Dr Crieve Coombs (Bristol) said that the discussion was evidence of the increased sense of responsibility in dealing with empyema and of the necessity for co-operation between physicians and surgeons.

SECTION OF OPHTHALMOLOGY

Wednesday, July 22nd

EYE INJURIES AND INTERSTITIAL KERATITIS

The President of the Section, Mr W Maillon Beaumont (Bath), in welcoming the members of the Section to Bath, referred especially to the number of American ophthalmologists visiting them, to whom also he offered a welcome. Mr W T Holmes Spicer (London) read a paper on eye injuries and interstitial keratitis. These cases, he said, involved complicated medico-legal issues. Most of the injuries alleged to be the determining causes were trivial—for example, from foreign bodies, slight abrasions—many of well planned operative procedures. Apart from the evidence of the stigmata of congenital syphilis, the eye symptoms might be perplexing. Where there was the predisposing diathesis a most trifling disturbance, even the administration of drops, had been held to precipitate attacks of typical interstitial keratitis, even in the untouched eye. Injuries occurred daily in large numbers in manufacturing towns, but the sequence of interstitial keratitis was rare. The occurrence of an attack in the untouched eye he held to throw doubt upon the true sequence of events, in some of these there were evidence of pre-existing ocular disease, in such a relapse was possible at any time. The alleged determining injury was probably only coincident with the time of likelihood of the manifestation of ocular syphilitic inflammation which would have become active, injury or no injury. If the characteristic signs of congenital syphilis were present even in infants were certain to appear at some time of life, dependent on the ripening of the organism, and the disease was syphilitic and not traumatic. The injury would not have given rise to the involvement of the eye unless the spirochaete was present in the eye. Mr Inglis Pollock (Glasgow) stressed the importance of exact clinical diagnosis. Mr A W Ormond (London) recalled the experience of war ophthalmic surgery. He thought that some 10 per cent of cases of corneal ulcers said to arise from injury were proved to be interstitial keratitis. Mr Freeland Fergus (Glasgow) said that the injury might be an exciting cause, but not the determining cause, of interstitial keratitis. Mr Bishop Harman (London) said all hinged on the question whether or not the attack of interstitial keratitis was in the balance or was certain to come at some date, injury or no injury. Mr C H Walker (Bristol) said he had seen cases of injury where the typical reactions of the trauma had almost cleared up when interstitial keratitis supervened. Dr E J Primrose (Glasgow) thought that if the injury and the onset of the interstitial keratitis were merely coincident, then the keratitis should be as frequent in the uninjured eye as in the injured eye, but this was not so, the majority appeared in the injured eye. Dr Wallace Henry (Leicester) referred to the alleged sequence of interstitial keratitis to general anaesthesia. Dr de Schweinitz (Philadelphia) thought that lowered resistance would be a determining influence in dating an attack. Dr R Kerry (Montreal) made some comments on treatment, and Mr Holmes Spicer replied.

Mr A W Ormond (London) read a paper on visual hallucinations of sane people, which was discussed by Dr Wallace Henry, Mr P G Dove (London), Dr A L Davis (New York), Dr Webster Fox (Philadelphia), and Mr Cyril Walker. Mr Bishop Harman (London) made a communication on phlyctenular conjunctivitis and keratitis, causes and prevention, which was discussed by Mr T H Breckerton (Liverpool). Dr Wallace Henry demonstrated an instrument for recording light minimum and light difference, and Mr A C Perreval (Newcastle-on-Tyne) discussed results obtained. Mr R Colley (Bath) gave notes

of a case of perforating wound of the eye with retention of a piece of glass, discussed by Mr. Cyril Walker, Dr. Chalmers Jameson (Bristol), Mr. T. H. Bickerton, and Dr. A. E. Davis.

Thursday July 2nd

Ocular Pain

Mr. A. Freeland Feigis (Glasgow) opened the discussion on ocular pain. These pains were mainly neuralgic in origin about the eye. Uncorrected errors of refraction were the cause of much pain. Drugs were disastrous, glasses were imperative. A defective image of positive convergence amongst varieties of muscular imbalance was a common cause of eye pain, and its correction was followed by speedy relief. A very large amount of ocular pain was briefly included in the word "sepsis," and these cases necessitated the most careful scrutiny of every factor. Itis and eyelitis were always septic in origin, their painfulness was in proportion to the septic reaction. An ordinary wound might cause a fair amount of pain, but that soon passed off, and as a rule caused no more uneasiness. In septic conditions the reverse was found. After a normal cataract operation the patient was soon comfortable, but sepsis was heralded by increasing pain. The pain of iritis was excruciating. Relief followed the use of opiates, atropine, and even hot applications. But permanent relief could only be secured by the accurate diagnosis and treatment of the cause. Corneal ulceration was a very painful affliction. Cocaine should never be used in these cases, it did not relieve deep pain, and had a most disastrous effect on the corneal tissue. Atropine was almost as bad. Bandages were bad, because they retained the septic discharges. Corneal drainage was to be promoted for this reason was invaluable, combined with free irrigation and protection by eyeshades. The secret of success in the relief of ocular pain lay in the discovery of its primary cause without this the most extensive medical equipment in drugs was ineffective. Mr. A. W. Ormond said that they might also consider the immediate relief of pain. What could they do to relieve the distress of the patient who would not and could not wait the scientific recovery of the primary cause of his trouble? Dr. Wallace Henry (Leicester) dealt with reflex pain, especially from dental troubles. Mr. Bishop Humm said that in his experience there was no better means for the immediate relief of pain than heat. Mr. Cyril Walker (Bristol) agreed, and described many ingenious and simple means for the application of steam. Mr. Lindsay Rea instructed the distress of psychical pain. Mr. A. S. Percival (Newcastle) remarked on the strange variable effect of diuretic in some cases it was wonderful, in others useless, and he could not discover the reason. Dr. Webster Fox (Philadelphia) said leeches had not been mentioned, they were old-fashioned but undoubtedly useful as adjuncts. Colonel Lister said he had never known leeches to fail, they were invariably used in India. Dr. Freeland Feigis replied that the immediate relief of pain was easy, its permanent relief was the point at issue and that depended on the primary cause.

Mr. Lindsay Rea (London) read a paper on the treatment of ocular syphilis which was discussed by Mr. Bishop Humm, Dr. E. J. Primrose, Colonel A. E. J. Lister, I.M.S. and Dr. C. B. F. Tilly. Mr. C. H. Walker (Bristol) read some notes on a case of amaurosis, and also showed an improved form of portable operating table. Mr. T. H. Bickerton (Liverpool) commented on the superior value of operating on the patient when in his or her own bed. Mr. A. S. Percival (Newcastle) read a paper entitled "Some of the things I don't know." In this he dealt with the puzzles exhibited in allied clinical disorders. Comments were made by Dr. Hugh Pollock, Mr. Bishop Humm, Dr. Peter Macdonald, Dr. Wallace Henry, Mr. T. H. Bickerton, Dr. J. W. Tudor Thomas, Mr. Freeland Feigis and Mr. Percival replied and gave a demonstration of tension and pressure as affecting an artificial eye. Mr. J. Burdon-Cooper read a paper on conservative treatment of glaucoma. He made no plea for non-operative treatment, he had no doubt of the necessity of operation but primary conservative treatment advanced the prospects of success of operation. Rise of general blood pressure, defects of metabolic processes, psychic disturbances un-

doubtedly necessitated a symptomatic change. The operation delayed them. Acute glaucoma could be reduced by the warm body bath and nitroglycerin administered by the mouth with local heat to the eye, and eserine. There was definite reduction of tension and operation was easier.

THE TUBERCULOUS SPINE

In the absence of Prof. J. Calve, owing to ill health, the duty of opening the discussion on tuberculous disease of the spine was undertaken on short notice by Sir Henry Gairdner (Alton) who referred to the disease which he had known of his years noticed in the severity of the deformity at the time of admission, no doubt the result of early diagnosis. The bulk of the tuberculous cases were infected by the bovine bacillus, and this was especially true of pueri do so. The chief principle of treatment apart from general hygiene and heliotherapy, were fixation, dorsal recumbency, and hyperextension of the spine. These principles were recognized and acted upon the detail of method was comparatively unimportant. He showed by means of lantern slides some of the types of splint in use at Alton, namely the bed, don't the wholebarrow, the Marion and the push and pull plants, the latter some of the full names being applied to various ingenious contrivances for carrying out the principles of treatment. The advantage of extension besides the correction of deformity was that it increased the expansion of the chest. Besides, as he did mostly with children, he was not in favour of Albee's operation. Relapse sometimes occurred if it failed, and when that happened correction was impossible. Albee's cases should be treated by aspiration repeated often is necessary. Mr. C. R. Endlestone (Oxford) thought better of Albee's operation for it was capable of supporting the spine when the lesion was so situated that no apparatus could fix it. It was, however, difficult or impossible to use when the deformity was very great. In such cases he preferred the operation of Hibbs, which, however, he found difficult. He had adopted the method of using osteo-periosteal grafts from the fibula placed over the side of the spine after doing Hibbs's operation. As showing the fatal results of septic psoas abscess in the adult he stated that of 9 cases admitted to the Wingfield Hospital 8 had died, whereas of 21 non-septic cases 16 were well some years afterwards. He thought that general hygiene to treatment was more important than heliotherapy. Mr. W. I. C. Pugh would restrict Albee's operation to adult cases. He criticized the theory of the procedure on mechanical and anatomical grounds as tending to throw pressure on to the intervertebral processes and then joints which were ill adapted to bear it, and yielded under it. If abscess persisted after Albee's operation it was difficult to treat, because it was not possible to allow the bodies of the affected vertebrae further to come together. He deprecated attempts to straighten out the kyphosis and separate the bodies of the diseased vertebrae. He made no such attempt, but put pressure above and below the kyphosis so as to produce compensatory curves, rather encouraging persistence of the kyphosis itself than not. Mr. Maurice Aitken (London) rather severely criticized Sir Henry Gairdner. He said that the splints shown by Sir Henry were dangerous in other hands than his, and that no man with less experience had a right to use them. One could not tell when the disease was really quiescent, and, therefore, in inexperienced hands such appliances were not safe. Mr. Aitken used bone grafts to prevent lateral movements, and found them most useful for cases of the cervical region. It was his routine method for cases over 14 years of age although it could not altogether replace support by appliances. He agreed with Sir Henry Gairdner that correction should be applied at the seat of deformity, and not above and below it. Mr. Pugh (Newcastle) realized the need for special hospitals and specialists, and commented on the long time during which treatment must be continued. Any evidence of the collapse and fusion of the vertebrae was indispensable to form an opinion of decided cure. As regards psoas abscess, when conservative

treatment was no longer of avail, clearing out of the contents and sewing up the wound had given him good results. Mr. ALVIN SMITH (Cardiff) had had bad results from opening and sewing up abscesses in adults. When priapism occurred, lumpectomy was necessary in cases which did not improve with prolonged rest.

Mr. R. C. ELMSHE (London) agreed with Sir Henry GUYAR that the type of cases now seen was less severe than formerly. Collapse of the diseased vertebrae was necessary—the opposite was harmful. As to Albee's operation, he would not do it before the age of 14 years, but in some cases it might be advisable earlier. Mr. FRANK (London) referred to the differential diagnosis of curvatures and showed prints illustrating the value of stereoscopic radiographs. Some doubtful cases proved to be of congenital or developmental abnormalities or of malignant disease, and some of these showed multiple lesions. Mr. McMURRAY (Liverpool) referred to cases of psoas abscess with discharging sinuses which showed no signs of healing until the patients were got upon their feet, when the sinuses closed. He would not use a bone graft under adult age. Dr. R. OSGOOD (Boston, U.S.A.) believed that the best results were to be obtained by recumbency for five to seven years, but as this was often impossible in practice the fusion operation of Hibbs or that of Albee was advisable, but not in the early stages or in young children. He referred to the value of x-rays in diagnosis and the importance of recognizing multiple foci. In adults the possibility of syphilis and new growths had to be remembered. Calve's operation was not dangerous, but it only succeeded if the pressure on the spine was caused by fluid. Mr. DAW (Leeds) said that in correction small compensatory curves should be aimed at. He used two lateral bone grafts—one on each side of the deformed spinous processes—instead of splitting the processes. Mr. HUTLEY MARTIN advocated correction of the kyphos itself. He believed that the gap filled up with fibrous tissue, which afterwards calcified. There was no great difficulty in doing Calve's aspiration through an intervertebral foramen and no danger to the cord. Sir William WHEELER (Dublin) would confine a modified Albee's operation to adults only. He regarded it as no cure but a means of splintage only. In one case he found six months *post mortem* that the graft was well fixed by new bone. In some cases of psoas abscess he had good results from a method of temporary stuffing with iodoform gauze, which he described. Sir Henry GUYAR briefly replied.

Mr. R. OLLERENSHAW (Manchester) read a paper on the Osgood-Schlatter disease. He showed, and illustrated his remarks with lantern slides, that all of some fifty cases were due to violence, similar to that which produced fracture of the patella in the adult. Avulsion of the tibial tubercle generally occurred in this injury. Dr. R. OSGOOD (Boston, U.S.A.) agreed with Mr. OLLERENSHAW as to the pathology of the lesion. He found that treatment with strapping was generally sufficient without the use of a plaster splint. A dead horse experiment showed that the tubercle could be detached by a violent strain on the ligamentum patellae without detachment of the ligament, the action of which was only slightly impaired.

SECTIONS OF SURGERY AND ORTHOPAEDICS

Friday, July 24th

JOINT DISCUSSION ON FRACTURES

On the third day the Section of Surgery held a combined discussion with the Orthopaedics Section on the treatment of fractures, with special reference to its organization and teaching. The debate on this subject resolved itself practically into a discussion of the merits and disadvantages of the system of segregation of fracture cases from all other types of surgical cases. The opener, Professor G. E. GASH, held that, while all was not well with the treatment of fractures as at present carried out in the general surgical wards of the big hospitals, the disadvantages of segregation, from the point of view of the teaching of students, more than outweighed any occasional advantage to an individual patient. He expressed himself as being against the growing tide of specialism, which first began when surgery was divorced from medicine, and now was proceeding to such

an extreme degree that many subdivisions of the surgical course of a student had already to be made. There was a danger that the student's teaching would be split up into numerous small water-tight compartments, in each of which he would have a smattering of knowledge, without being at any time during his surgical training properly instructed in the broad principles of surgery in all its branches. Sir ROBERT JONES followed with his now familiar plea and argument in favour of segregation and the adoption of the "fracture service" already in successful operation in many American and a few English hospitals. He did not agree that the teaching of students need suffer by this change, and pointed out that the welfare of the patient should in any case be the first and only consideration. The vastly improved results obtained in the latter part of the war by those who were specially trained in the treatment of fractures was in itself a sufficient indication for his proposal. It was not suggested that the head of the fracture service should necessarily be an orthopaedic surgeon, but much that the surgeon to whose care fracture cases were entrusted should be specially interested in the treatment of fractures. In many general surgeons were competent and willing to fulfil this role and thus relieve their professional brethren of the responsibility for a type of case in which they took little interest—for it could not be denied that in many hospitals the fracture case occupying a bed in a general surgical ward was regarded as an incubus to be got rid of at the earliest possible opportunity. Mr. S. W. DAW gave some details of the working of a scheme of the type advocated by Sir ROBERT JONES at Leeds, and he pointed out that the efficiency of the teaching of students necessarily varied with the efficiency of treatment, and Dr. OSGOOD of Boston gave details of the working of his own fracture service, which was supplementary to, and in no way interfered with, the treatment of fractures by those general surgeons of the hospital who cared to undertake this type of work. Mr. H. WADE, Mr. H. PLATT, Mr. H. A. T. FRANK, Mr. R. C. ELMSHE, Mr. W. R. BISTON, and Dr. BRAIN of Montreal all spoke in support of the segregation scheme, while Mr. MAY PAGE, Mr. H. H. SUMPSON, Mr. GWYNNE WILLIAMS, and Mr. McADAM LEECE all pointed out various difficulties, in some cases local, which they foresaw in the working of the scheme. Professor A. W. SHIEN advocated a large surgical team at each big general hospital, to include amongst other experts a fracture expert whose services could be called upon when necessary, without establishing a separate fracture service. Professor A. FULLERTON described the admirable results obtained in his own general surgical wards at Belfast, but Sir ROBERT JONES, in his reply, pointed out that Professor FULLERTON held all the necessary qualifications, including enthusiasm for the work, which he had laid down for the head of a fracture department.

SECTION OF PUBLIC MEDICINE

Thursday, July 23rd

HYGIENE OF FOOD MANIPULATION

THE discussion on food manipulation in relation to health was opened by Dr. W. G. SAVAGE, with the President, Dr. EUSTACE HILL, in the chair. Dr. SAVAGE said he was not satisfied that there was evidence to justify the view that had been expressed by some writers as to the deterioration of the nutritive qualities of foodstuffs as a result of manipulation, especially as a result of canning and other methods of preservation. Preservation of food was also intensely necessary, and it was important to consider carefully what methods were admissible and what kind and degree of control should be exercised. With regard to bacterial contamination, of course, the risk of contamination was strictly proportional to the amount of handling, and his experience led him to believe that dust and other forms of air-borne contamination were less important than actual contact with human hands. It was of the utmost importance that the food should be initially sound, and it was known that the *Bacillus botulinus* only attacked fruit which was already damaged. Food could be classified according to its liability to bacterial infection as follows: (a) Food which is a non-multiplying medium for bacteria and is subsequently cooked, such as ordinary cereals, this is the least dangerous form (b) Food which is a non-multiplying medium, but is not

Professor Leonard Hill gave a very valuable address on the influence of sunlight and artificial light on health. He described the measurement of wave lengths and specified the wave lengths that influenced the human body. Visible heat rays were capable of penetrating the skin and warming the blood but dark heat warmed the surface only whence the importance of open fires. The action of light and ultra-violet rays was assisted by heat but it was essential to avoid heat in the treatment of febrile cases of tuberculosis. Ultra-violet rays were derived from blue sky and white clouds as well as from direct sunlight and Professor Hill described the method of measuring such radiation by the bleaching of a solution of methylene blue in acetone. Observations of this kind showed that the amount of radiation at Kingsway was on an average only about one-third of that in the country. By means of coal smoke glass windows, and clothes they deprived themselves almost entirely of ultra-violet radiation and all their brick-built hospitals were out of date. The way to eliminate tuberculosis in cattle was, not to kill the affected animals but to give them fresh air and light treatment as they did to human sufferers. Dr Dixon gave his experience of heliotherapy in tuberculosis, and Dr Doris Colebrook described the work now being done with light treatment at the Islington Child Welfare Centre.

The author tells us in his preface that his book is intended to be a companion volume to textbooks on forensic medicine, that it does not cover the whole subject and merely represents some of the cases and specimens with which he has been accustomed to illustrate the lectures given in Edinburgh.

University. But it is exactly these features that make the book so valuable and will assuredly place it among the standard works on the subject. It is the difference between reading about the signs and symptoms of some disease or injury and standing by the bedside having these facts pointed out and learning the conclusions to be drawn from them. We have nothing but admiration for this excellent manual. It is worthy of the distinguished author and the great school to which he belongs.

ADMINISTRATIVE AND ECONOMIC PROBLEMS IN TUBERCULOSIS

In the small compass of the sixty-three pages of *Papworth, Administrative and Economic Problems in Tuberculosis*, the late Sir GERMAN SIMS WOODHEAD, the late Sir CLIFFORD ALBERT and Dr VARRIOR-JONES provide thought for much fruit-searching as to the efficiency of the existing system of tuberculosis dispensaries and sanatoriums. The weakness of the dispensary system is shown with unflinching candour, the patients are commonly seen rapidly at the dispensary, which is thus apt to become a field for little more than "an out-patient department stocked with drugs which are mostly placebos or an annex of an office for compilation of statistics." Sanatoriums are designed for early cases, but they are, we are told, seldom or never put to this use properly. 90 per cent or more of the inmates are past the early stage, and the sanatorium is in danger of becoming a hospital for incurables. Sanatorium patients are not cured by their residence, and it is more accurate to say that sanatorium treatment slows the progress of tuberculosis rather than that it arrests the disease. When a patient goes home and has to face competition against healthy workers, a relapse is very prone to result. It is difficult to get hold of the early cases, for, as Sir JAMES FOWLER epigrammatically says in the preface, "the working man has no time to be an early case of tuberculosis."

Most people are fascinated by the hope of a cure and both individuals and public bodies unfortunately are left quite cold by prevention. On leaving a sanatorium the patients should live in a settlement where they can earn their living by a properly restricted activity suited to their diminished strength, that this can be done has been shown by the village settlement known as Papworth. The book has been admirably and entirely printed at Papworth by the Papworth Press, an achievement described as probably unique in the annals of printing.

HUMAN CONSTITUTION AND DISEASE

Dr GEORGE DRAPER's monograph *Human Constitution and its Relation to Disease*¹ is the first of a series planned to deal with the whole subject, and is the outcome of five years' intensive work at the Presbyterian Hospital, New York. As the word "constitution" has been rather vaguely used in different senses it may be well to quote the meaning that the author attaches to it. "The aggregate of hereditary characters influenced more or less by environment which determines the individual's reaction, successful or unsuccessful to the stress of environment." The influence of the subject's constitution in rendering him susceptible to disease is present to the mind of Hippocrates, and was studied by John Hunter, Addison, Laycock and Jonathan Hutchinson, but the rise of bacteriology diverted attention from the internal to the external factors of disease. Now however interest has been recalled to the influence of the constitution as a factor in the incidence of disease and in this swing of the pendulum the increasing knowledge of the endocrine glands has played a part, Dr Draper indeed considers it certain

that no method of studying constitution is complete or even possible which on its consideration of the endocrine glands.

The hereditary characters which make up an individual's constitution have been grouped for convenience into four main categories or, as they are called, "panels"—namely, the anatomical, physiological, psychological, and immunological. The headings of the investigations to be undertaken in each of these divisions are set out, but this volume is devoted to the anatomical panel which is dealt with in great detail. Anthropometric measurements in the past have been used in order to obtain the characteristics of the races of mankind, but in this research they have been applied to certain diseases—namely affections of the gall bladder, gastric and duodenal ulcer, nephritis and high blood pressure, pernicious anaemia, asthma, tuberculosis, and acromegaly. The most modern anthropometric technique has been employed on a uniform plan and the data thus obtained have been analysed on biometric lines by specially qualified collaborators. Thus instead of investigating geographical races disease races are studied, and charts of the various indices, constructed for males and females, in each disease are analysed and the results are discussed, and provide points of interest. There is as much discrepancy in the cephalic index between some of the disease groups as there is between some geographical races. The numerous tables and charts prove, if evidence were wanting the enormous amount of work that Dr Draper and his fellow workers have carried out, and raise important issues.

The need felt in other quarters for information about a uniform method of investigation has been responsible for the publication of this instalment of a series which cannot fail to be of great interest to all medical workers.

SURGICAL TREATMENT OF BRONCHIECTASIS

GUIBAL's book on the surgical treatment of bronchiectasis forms one of a series of monographs which is being published by Masson and Co. to supplement the larger textbooks. The series will deal exclusively with matters of practical medical and surgical interest. When any particular branch of technique has made such progress as to render the ordinary textbook account out of date in certain particulars, it is proposed in this series to issue a review of the subject, including not merely what is new, but, in concise and systematic form, the whole practical aspect of the subject. Each volume, therefore, will contain a summary of the views current at the moment of publication, and, being of small size and limited scope, will be readily brought up to date. If placed in efficient hands the realization of the project should supply a genuine need in these days of rapid advance.

The present volume, dealing with the surgery of bronchiectasis, carries out the intention of the publishers very successfully. After defining the types of bronchial dilatation which come within the scope of surgery, Guibal classifies and describes the various surgical measures that are employed at the present time. Under the general headings of operations for compressing the lung, operations for drainage, operations for producing atrophy of the lung, and operations for the removal of the diseased lung tissue, the several surgical procedures are described in full practical detail, with diagrams and illustrations necessary to render the accounts intelligible. In this way are described artificial pneumothorax, pleuro-pneumal decollement, extrapleural thoracoplasty, pneumotomy, ligature of branches of the pulmonary artery, and partial pneumectomy. The technical directions for each operation are carefully laid down, in locations and contraindications are discussed, and possible complications and their treatment considered. Due attention is given to the after-treatment, and the results of the several operations are shown by a reference to the experience of surgeons who have worked in this branch of the subject. As a general survey of present-day surgical possibilities in bronchiectasis the book should be welcome.

³ The mention of quotations is not in itself a responsibility for the work which we believe to be new and is certainly unneeded.

LIVING MATTER

KUNSTLER and PREVOST's work *La Matière vivante* contains a lucid account, following Dujardin (1835) rather than Purkinje (1840), of present views on the structure of protoplasm or sarcodae, as the authors prefer to call it. In the opinion of many, living protoplasm is a simple chemical substance of colloidal nature, composed of a fluid basis containing minute granules. Others consider that this conception is insufficient to explain the phenomena of life. They argue that the properties of simple matter exhibit a uniformity that is not observed in the phenomena of life, that the peculiar property of living matter is function, and that there can be no function without organization. They hold that although inert matter may be made to subserve function, it can only do so through the intermediary of man, whereas in living matter the organization is natural. A simple illustration is given to render this clear. A balloon is composed of material possessing definite properties, but its power of ascending depends not on any inherent property, but is a new fact resulting from structural organization. The authors, therefore, hold that protoplasm has a definite organic structure, and their book is devoted to a demonstration of the anatomical appearances, as seen under the microscope, which lend support to this view.

The first observations were made in 1880 on *Flagella oxyuris*, the protoplasm of which was found to consist of regular parallel lines of dark staining points embedded in a clear substance. Studied in the unstained living cell the protoplasm appeared to consist of a fundamental substance enclosing innumerable minute cavities (vacuoloids). Further analysis showed that the fundamental substance consisted of minute globules arranged in lines (fibrilloids) and that the chromophil bodies lay in the interstices between the fibrilloids, sending out processes at their periphery and possessing a form somewhat comparable to that of minute amoebae. The chromophil bodies could not therefore be regarded as mere granules, but formed part of the organized structure of the protoplasm. In a great number of organisms the cells exhibit the stable and compact structure described, but in many of the protozoa the central part of the protoplasm consists of a fluid containing a number of spherules, isolated or grouped into masses. According to the authors this form of protoplasm arises from a fluid infiltration which has the effect of isolating the vacuoloids with their contained chromophil bodies, which then float freely in the liquid. To the isolated bodies, consisting of a single chromophil body with its surrounding zone of fundamental substance, the authors have given the name "spherules," and they appear to regard them as the units of structure of the protoplasm. The book is illustrated by numerous good photomicrographs, and these certainly convey the impression of a definite organized structure, although the finer details are difficult to follow.

Having described the two fundamental forms of protoplasm, the compact and the fluid, the authors proceed to indicate the various changes of form which the units of structure undergo under varying conditions, and also the evidences of organization within the cell pointing to a differentiation of function among the units. The latter is best seen in the unicellular glands of Hippelina. These glands exhibit a well marked physiological division of labour within the protoplasmic mass, the primordial, undifferentiated part of the protoplasm is displaced to the periphery, while the functional part is connected with the excretory duct by numerous canaliculi which traverse the protoplasm and terminate in a common reservoir. The authors state that the details they describe are readily observed and require no special histological aptitude. The account they give is of much interest and deserves the attention of all who are occupied in cytological problems.

NOTES ON BOOKS

WE always welcome a book from the pen of Dr CABANES, for his enthusiasm and industry take him into the by paths of medical history which save for his researches, would remain unexplored. Only a few months ago we had the pleasure of reviewing his book *Au Chevet de l'Empereur*, and

now we have before us, another volume dealing with the inexhaustible subject of the career of the great Napoleon. In this volume Dr Cabanes gives an account of the intimate life of Napoleon which but for the paramount place occupied by him in the minds of men could have had only a passing interest. With Dr Cabanes as our experienced guide we are shown in the way in which Napoleon ate his food, how he worked in his cabinet, how he slept, and how he loved. In all the various small routine events of Napoleon's life the psychology underlying each operation is fully considered, and this perhaps allows us to understand more fully the peculiarities of that mighty brain. Of more interest to medical readers are the chapters dealing with the attitude of Napoleon towards medicine, physiology, and science. The exact brain of Napoleon had not much sympathy with physicians, who perforce were practising an inexact art and science, and perhaps his view concerning physicians might be summed up in the words of Voltaire, who said that "Doctors were people who poured into bottles of which they knew little, things of which they knew less." But Napoleon's attitude to science was far different, and no great ruler ever gave to it more encouragement. Indeed his foresight in fostering science is the best evidence of his great ability as a statesman, and is ably set forth in this book. Dr Cabanes has also begun the publication of a new edition of his book issued first some five and twenty years ago *Les Curieuses de la Médecine*. It is, he announces, practically a new book and there are to be three volumes. It is a sort of commonplace book consisting of notes and anecdotes thrown loosely together under sub headings. The first volume, now before us, deals with the skeleton the second is to be concerned with the organs of sense, and the third with the functions of the body—locomotion, speech, the organs of nutrition, and so on.

Dr MAURICE TOTTIER has produced a small volume containing a history of gastric secretion from the time of Hippocrates to the present day. Six main periods are recognized. The first extends from the dawn of medical history to the time of Paracelsus, this is the Cerebral period in which the physiology of Galen dominated medical thought. It includes such writers as Orribasius, Paulus Aegineta the Arabians, and those connected with the school of Salerno. The second or chemical period is that in which Paracelsus, van Helmont, and Sylvius Du Bois (or DeBooe) flourished. They were the pioneers of the chemistry of gastric digestion. In the third or mechanical period putrefaction, fermentation, and trituration were emphasized, and the chemical aspect ignored, it is notable for the researches of Harvey, who had a profound influence on his contemporaries especially Borelli, Baglivi, Bellini, Redi, Cole, and Descartes, who were all more or less directly his disciples. In the fourth period, which is that of gastric acidity, Rammur, Spallanzani, and John Hunter revolutionized the current theories of digestion by substituting an idea of chemical dissolution by an undissolved acid in place of that of fermentation and putrefaction. In the fifth period Beaumont's classical researches on Saint Martin showed that an acid was produced by the gastric mucous membrane, and that this acid was hydrochloric acid. Finally, the sixth period, which is that of pepsine and experimental fistula, is remarkable for the work of Schwann, Blondlot, Claude Bernard, and Pavlov. The work is attractively written and interspersed with numerous portraits and other illustrations.

It is not at all clear why Mr J. ANGUS PARSONS, consulting surgeon to the Chelsea Hospital for Women, has selected the title *Evolution Explained* for the little book he has recently written. Actually it consists of a domestic presentation of the doctrines of evolution followed by a general survey of a number of unrelated subjects, such as future existence, religious toleration, socialism, fatalism, and inventions. Nothing is explained, not even the progress of which we are told in Chapter XVI where we read, "Man has slowly improved and developed from the animals and is now in the image of the anthropoid apes. It is a blasphemous idea to think that this can be the image of God." We suggest that "Evolution Affirmed and Other Subjects Commented On" would have been a more accurate, though more emblematic, title. Some sceptical readers also might have been more easily convinced by the hygienic and sociological arguments of the later chapters of the book had they been persuaded in earlier pages that the laws said to govern the physical life of plants and animals can fittingly be applied to the mental life of man. Though generally in agreement

with the author's conclusions, we have looked in vain for evidence which less sympathetic readers might justifiably have demanded.

In his little work entitled *A Study of Masturbation and its Reputed Sequelae* Dr JOHN F. W. McLAGHER, neurologist to St Mary's Hospital, Brooklyn, agrees with the majority of modern scientific investigators that most of the so-called dangers and sequelae of the habit are exaggerations or myths which have been handed down to us from the writings of Tissot and his contemporaries in the last quarter of the eighteenth century. Most of the cases designated "masturbational insanity" by earlier writers are, as Brill has shown, really examples of dementia praecox. Dr McLAGHER, however, points out that while masturbation is almost a normal phenomenon in the child and adolescent, it is not to be so regarded in the adult inasmuch as it indicates a failure of psychosexual development. In discussing treatment the writer, who has little faith in drugs and still less in surgical measures, deals with the subject chiefly from the standpoint of the psycho-pathologist recommending sympathy and encouragement rather than censure and punishment.

Internal evidence would lead one to believe that while the singer of *Blue and Other Verses* lives in the Antipodes he was not born there, for time and again we have memories of the old country tugging at his heart strings.

I saw once more the oak tree gaunt
The blackened hedge same
Inhaled the scent of daisy leaves—
The breath of a sunny time
It's strange that for such simple things
One's heart should seem to care
But—Home is ever there!

The poem which gives the title to his volume is not his most successful effort in rhyme. After descending on various blues the singer finishes

All this is naught to that divinest hue
When all the hues of earth melt into Blue

which seems somewhat more obscure than Browning's famous—

Hobbs hints blue—straight he turtles' eat
Hobbs prints blue—claret crowns his cup
Aokes on daisies Stokes in azure seats—
Both gorge Who'll heet the murex up?
What puridge had John Keats?

But, as a rule, Mr EDGBASTON is easily understandable, and is at his best perhaps in his London "The Pipes of Pan."

The pipes of Pan! I hear them yet!
When in the city's roar I lie
My fancy has unbridled rein
I hear through voice of mist and dream
The sweet lilac note I once forgot

MEDICAL AND SURGICAL APPLIANCES

A Metal X-Ray Tube

ONE of the exhibits which excited interest at the recent International Congress of Radiology in London was an x-ray tube representing a very considerable departure from the usual construction, inasmuch as it took the form of a metal cylinder or large electric torch about two and a half inches in diameter the beam coming through the window at the end. This tube called the Philips Metalux is manufactured by Philips Glow Lamp Works Limited (Eindhoven, Holland) represented in this country by Philips Lamps Limited (60 Wilson Street, Finsbury Square, E.C.2). The tube is declared to be protected so completely by its own lead sheet that no x-rays emerge except by way of the primary beam which is automatically centred at the window. The advantages claimed are that a tube of this construction renders superfluous a protective bowl that only a small clip for fixing the tube on its support is necessary and that its fragility is much less than that of glass tubes. The tube which is produced in several types for diagnosis and therapy, claims also to be able to support heavier currents than glass tubes by reason of the special construction of the anticathode.

Ultra Violet Lamps

Various types of lamps for use in light therapy have been placed on the market by Kelvin Bottomley and Band, Limited (51-52 Fenchurch Street, London, E.C.3). The light source in each case is a quartz mercury vapour lamp working at atmospheric pressure and the construction varies according to whether general light bath treatment, local treatment in conjunction with quartz transmitters and compressors or the irradiation of a number of patients simultaneously is desired. In one form the lamp is made for suspension from the ceiling to give a general irradiation; this is designed for the use of public health authorities in children's welfare clinics. All the lamps are of British manufacture throughout and they have many little adjustments and conveniences which make for ease and efficiency in manipulation. The running costs also would seem to be comparatively small.

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER

London County Council

THE Royal Commission resumed on July 10th, when evidence was tendered by the Hon. W. SIDNEY, J.P., and Mrs. DUNN GARDNER, J.P., respectively chairman and vice chairman of the Mental Hospitals Committee of the London County Council.

The witnesses stated that in the opinion of their committee which had been endorsed by the Council it was very desirable that the duty of providing for temporary treatment without certification (the principle embodied in the Mental Treatment Bill, which the Council had supported) should be undertaken by the same authority and the same branch of administration as that which was responsible for the mental hospitals themselves. They also thought it desirable that any legislation providing for early treatment of mental disease should authorize the reception into institutions of patients incapable of volition as well as those—the voluntary patients proper—who were willing to submit to treatment. The London County Council had also endorsed the view that in every case in which an order for compulsory detention of a person of unsound mind was made two medical certificates should be necessary for presentation to the judicial authority who was asked to make the order, and that one of these certificates should be given by a practitioner who had been approved specially for that purpose.

The witnesses went on to give some particulars with regard to medical treatment in the mental hospitals of the London County Council. They said that much more attention was paid now to actual treatment than was the case formerly. The number of medical officers had been considerably increased in recent years. In institutions with 2,000 or more patients eight assistant medical officers were allowed. Every inducement was given to young medical officers joining the service to qualify specially in the knowledge of psychological medicine by obtaining a diploma in that subject. The Council had arranged courses of lectures—seven courses had already been held, and the eighth was in progress—at the Maudsley Hospital for post graduate students in connexion with the diploma. Leave was also given for medical officers—not exceeding four at a time—to attend for a three months course of clinical and pathological work at Maudsley with a view to their being better acquainted with the latest methods of treatment in mental disease.

The chief pathological laboratory in connexion with the London County mental hospitals was at Maudsley. Its director was Dr. Golla who had succeeded Sir Frederick Mott. Medical officers from the mental hospitals of London were seconded to work at this central laboratory with a view to their undertaking special research. A local laboratory suitably established was provided at each mental hospital, and recently it had been arranged for Dr. Golla from time to time to inspect the laboratories and report on the work done.

In the case of nurses employed by the Council, every effort was made to assist them to qualify by gaining a diploma in mental nursing. The Council had improved the pay and hours of duty of the nursing staff in acknowledgement of the onerous and often distasteful tasks they had to perform and with the hope of obtaining a satisfied as well as satisfactory staff. One of the greatest difficulties which the Council had to contend with was the recruiting of a sufficient number of suitable women for positions on the nursing staff.

The Association of Municipal Corporations

On July 11th Sir LEWIS BEARD, town clerk of Blackburn, gave evidence on behalf of the Association of Municipal Corporations.

The witness pointed out that the net yearly increase in patients requiring accommodation in mental hospitals in England and Wales from 1920 to 1923 was 3,565, and it was evident that this growing demand would soon overtake all the ordinary resources in the way of accommodation. His corporation therefore wished to suggest, as a palliative measure until building costs became less burdensome for local authorities, that use should be made of vacant residential accommodation at institutions now maintained by the Poor Law guardians. Such accommodation was quite suitable for housing the more chronic type of case under proper supervision, and thus spare mental hospitals would be released for cases in which treatment was likely to prove remedial. The selection of old chronic cases which should be transferred into these erstwhile Poor Law institutions would have to be undertaken with great care and of course would have to be in the hands of medical officers, if hardship in individual instances was to be avoided. Sir David Drummond asked if there would not be a competition between mental hospitals and voluntary hospitals, many

of which latter also desired to utilize the accommodation available in Poor Law institutions but the witness said that what he had in mind was not the infirmary wards but the ordinary residential wards, which were quite suitable for the reception of patients who were not physically ill, but who were senile or suffered from chronic mental disorder.

Passing to another matter he said that his association supported the Mental Treatment Bill and was of opinion that there ought to be provision for the treatment of incipient cases without certification. Speaking on his own behalf he suggested that local authorities might usefully undertake the course of instruction for the public in the nature of mental disorder and the need for early treatment just in the same way as they already undertook a certain amount of health propaganda. This would help to dispel the fantastic and morbid notions which many people held with regard to insanity and would help to break down that sharp division in the public mind between mental and other illness. The Chairman (Mr H. P. Macmillan) remarked that this was a new and interesting suggestion.

The witness also spoke out of his experience of visiting committees, the name of which he wanted altered to mental hospital committees because visiting committees suggested a casual inspection when their actual duties were much more important. Asked whether in his experience of visiting committees patients had been discharged by the committees although the medical superintendent had not recommended such discharge he said that he had known this occur but not frequently. He was opposed to the view that certain functions of the Board of Control at present advisory should be made mandatory because he wanted local authorities to have freedom of action in matters of detail. If they were not overweighed by official regulations they might make interesting experiments which in course of time, being of proved value would be embodied in the general system of administration. That was the way in which many things, now universal and obligatory had come about.

The Commission adjourned to a date subsequently to be announced.

THE STATE OF THE PUBLIC HEALTH

SIR GEORGE NEWMAN'S REPORT FOR 1924

ENGLAND AND WALES

[Second Notice*]

THE INSURANCE MEDICAL SERVICE

MORE space than usual is devoted to the insurance medical service, and an excellent summary is given of the working of medical benefit. This section of the report begins with the statement that ever since the inception of medical benefit twelve years ago the service has laboured under many disadvantages, and has been obscured by a cloud of misconceptions and misunderstandings, especially as regards the position of the panel practitioners. Reference is made to the serious effects of the war, which interrupted all progress at the very beginning but it is claimed that with the end of the war, followed by the constitution of the Ministry of Health and the revision of the terms of service, conditions have steadily improved.

Among other improvements are noted the new method of calculating medical remuneration, the new scale of remuneration arrived at as the result of arbitration, the new system of medical records, the increased efficiency of the service due to the work of the Regional Medical Staff, the granting to insured persons of the right to change doctors at any time with fewer formalities, the reduction of the maximum number of insured persons which an insurance doctor may accept from 3,000 to 2,500, and the more satisfactory definition of the range of services that may be required from the doctors. The services now required are defined to comprise "all proper and necessary medical services other than those involving the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess." Broadly, the service works on the lines of private medical practice and while the panel doctor is "the family

doctor to the insured," his more intimate relation to the State and the public health service make him a most important part of the State organization in medical

Numbers Entitled to Medical Benefit

The total population of England and Wales in 1924 was 38,690,000 and the number of insured persons entitled to medical benefit was 13,672,000—that is, rather more than a third of the total population. Insured persons may obtain medical treatment in one of three ways: (1) from a general practitioner who has on their list 12,629,650; (2) from approved medical institutions which existed when the Act of 1911 was passed and which now treat 162,100 persons; and (3) under arrangements for medical treatment made with the consent of the Local Insurance Committee by individuals who receive from the committee a contribution towards the cost of treatment actually obtained. These numbered in 1924 about 37,100.

The number of insurance practitioners in 1924 was 13,157, and the average number of insured persons on their lists was 980. The approximate number of chemists' shops for the supply of medicines and appliances was 9,650 and the number of prescriptions dispensed was about 43,793,000. The total cost of medical benefit was £8,200,000 of which approximately £6,475,000 was for the remuneration of the doctors and £1,725,000 for medicines and appliances.

The insurance doctors are not a selected class of practitioners as any medical man or woman who comes on the *Medical Register* has a statutory right to enter the insurance medical service and it is specially noted that the relation of the panel doctor to the Insurance Committee is in no sense that of employer and employee.

Returns and Documents

Referring to some criticisms of the service, the report says it is necessary for the insurance doctor to furnish certain returns to the committees, but it has been one of the chief objects of the department to reduce these formalities to a minimum. We are reminded that some of these formalities are necessary, not least in the interests of doctors themselves. Doctors may not be heard from the early days of the insurance system that it is bound up with red tape, that the doctors are overwhelmed with clerical work and run grave risk of having substantial sums withheld from their remuneration for what they call "technical breaches" of the regulations. Dealing with the documents required from the doctors, mention is made of the medical prescriptions for medicines and appliances, certificates of incapacity, and the records of patients' illnesses and of attendance and services given. Nothing need be said of the prescription but it is observed that the form, size and management of the certificates of incapacity were arrived at in consultation with representatives of the doctors so as to reduce the clerical work to a minimum essential.

The report deals at considerable length with the form of medical records and its requirements. This was devised by a departmental committee under the chairmanship of Sir Humphry Rolleston, which included representatives of the insurance doctors, and a protest is made against the idea that the record-keeping is an unnecessary waste of time in clerical work required in the alleged interests of bureaucratic red tape. It is asserted, so far from that being the case the record-keeping is a procedure which every careful and methodical practitioner would, and in fact does, adopt in his practice. We are told that the records are not only of statistical value, but are essentially clinical documents, serving not only to save the doctor from "the pitfalls of forgetfulness" as to his patients' illnesses, but useful for the guidance of other practitioners who may follow him, and the "illuminating effect of the late Sir James MacLennan" is held up as a model to panel doctors, presumably in part because he kept records of his cases when he was a general practitioner. In the case of many panel doctors with 1,500 to 2,500 persons on their lists, one cannot help wondering whether the record ends, as they are kept or are ever likely to be kept, or indeed as they could with the best intentions, possibly be kept, on any form a reliable basis for statistics or be of anything beyond trivial use in the future. For one

* First notice, BRITISH MEDICAL JOURNAL July 11th p. 83

thing, it is doubtful whether in busy times more than a fraction of the visits and attendances rendered are entered on the cards even though there is a possibility that the number of attendances may be taken into consideration in fixing the doctors' remuneration.

In addition to the records, there are mentioned the supplementary forms used when a doctor accepts an insured person on his list, the receipts on the special forms for payments by persons whose right to medical benefit is in doubt, the form to be sent to the Committee when it is proposed to charge a fee for operation or other special service, the reports to the regional medical officer when a patient is referred for examination, and the reports to the tuberculosis officer about tuberculous patients. All these records and reports form a cumulative total of clerical work which appears to be greatly underestimated by the insurance department and by Sir George Newman, and his apology in the report is not likely to be wholly satisfactory to many panel doctors.

Disciplinary Procedure

A good deal of attention is given to the various disciplinary measures in use in case of breach of the terms of service, failure to provide proper treatment, or conduct possibly calling for removal from the medical list, and the procedure in each case is explained. Questions of this kind may arise in three different connections.

First, the Insurance Committees have the responsibility of dealing with any question between insurance doctors and insured persons, or questions raised by approved societies as to the action of doctors with regard to medical certificates, all these questions are referred to the Medical Service Subcommittee, which may also deal with any matter relating to the administration of medical benefit. Secondly, where an insurance doctor is shown after investigation by the Medical Service Subcommittee or otherwise to have failed to carry out his terms of service, the Minister may withhold from the doctor's remuneration such sums as he thinks fit. In the third place, the Minister may remove from the medical list, after such inquiry as is prescribed in the regulations, any practitioner whose continuance on the list would be prejudicial to the efficiency of the service.

The constitution of the Medical Service Subcommittee is discussed, and the types of cases dealt with by the subcommittees are broadly grouped under three heads: (1) neglect of patients, (2) fee charging, and (3) defective certification. In 1924 these subcommittees dealt with 404 cases, as compared with 500 in 1923, and the Minister decided to withhold varying amounts of money in 119 cases. In addition monies were withheld in 17 cases where practitioners had failed to keep the medical records, and in 14 cases where there had been failure to furnish information required by the regional medical officer. In 23 cases doctors appealed against decisions of the Insurance Committees, and in 9 of these the appeal was allowed, in 11 it was dismissed, and in 3 withdrawn. There were also five appeals by doctors against decisions of the Insurance Committees that they had been guilty of excessive prescribing, in two of these the appeal was dismissed, in one it was allowed, and in two the amount surcharged by the committee was reduced.

In 1924 representations were made that the continuance of nine practitioners on the medical list would be prejudicial to the medical service of the insured. In one of these the Minister refused even to hold an inquiry. In the other eight an inquiry was held, and as a result the Minister decided to remove four practitioners from the list and not to remove the other four.

Regional Medical Staff

The Regional Medical Staff is next dealt with, and it appears that in 1924 there were 183,846 insured persons referred to the staff for examination where there was some doubt as to incapacity for work. Of these, 181,990 were referred by approved societies, 581 by Insurance Committees, and 1,275 by the panel doctors themselves. In all such cases the practitioner concerned receives notice of the time and place of the examination so that he may be present if he so desires, and is required to send to the regional medical

officer before the examination a concise statement in writing of the history and condition of the patient. In addition to these "incapacity cases" the staff dealt with 2,270 "consultation cases"—that is, cases where the question of incapacity did not arise but where it was simply desired to obtain a second medical opinion. Of these, 1,803 were sent by approved societies, 4 by Insurance Committees, and 465 by practitioners. Thus the total number of insured persons referred to the staff has increased every year since its inception, and in 1924 was 185,116.

Another important duty of the staff is the examination of the medical records, and the number of visits made for this purpose was 4,357. It is stated that the regional officers have found a growing appreciation among practitioners of the clinical value of the records and the standard of record-keeping continues to improve.

The staff is also responsible for the inspection of the records required under the Dangerous Drugs Act, and for this purpose 4,302 doctors and 68 hospitals have been visited. In addition, 24 doctors who appeared to have prescribed or supplied these drugs in excessive quantities were visited at the request of the Home Office to obtain an explanation.

Attention is drawn to an inquiry now proceeding as to the great rise in the cost of insurance prescribing since 1920, but no definite conclusions have yet been obtained.

Additional Benefits

It is mentioned that in 1924 approximately £800,000 was spent in "additional benefits" by approved societies who had a disposable surplus, as compared with £500,000 in 1923, the increase being largely due to the growing popularity of dental benefit. Substantial sums were also paid by the societies to hospitals or convalescent homes in respect of the in-patient treatment of their members.

In conclusion, Sir George Newman lays emphasis on the public importance of the insurance medical service and his profound belief in its value. He thinks that one of the most pressing needs is the inclusion of consultant services, and not until that is accomplished will the full capacity of the insurance medical service for public usefulness be made manifest.

THE POOR LAW MEDICAL SERVICE

Turning next to the Poor Law medical service, the report points out that medical assistance is provided for the poor in the form of either domiciliary or institutional treatment, that the responsibility for providing this falls on some 650 boards of guardians, and that the definition of what is meant by "the poor" in this connexion was laid down in 1910 by the Local Government Board as follows:

A person who is not destitute in the sense that he is entirely devoid of the means of subsistence may yet be destitute in that he is unable to provide for himself a particular form of medical attendance or treatment of which he is in urgent need.

Domiciliary treatment is given by the district medical officers, who number in England and Wales about 3,500, most of these being salaried part-time general practitioners, though in a few populous districts the guardians have provided whole-time officers.

For institutional treatment there are something like 715 institutions and infirmaries, with accommodation for about 132,000 cases, but as changes are constantly being made these figures are only approximate. As regards tuberculous cases, it is stated that the majority of the pulmonary cases under treatment by the guardians are in the advanced stage. Early cases do not appear to enter the Poor Law institutions in any great numbers, and there are in fact few institutions under the guardians so designed or situated as to offer reasonable facilities for the sanatorium treatment required in early cases of pulmonary tuberculosis. Regret is expressed that arrangements for co-ordination with the local health authorities are not as complete as is desirable. Attention too is directed to the scanty records of cases kept by the medical officers of the Poor Law institutions, and it is recalled that a scheme is now in hand for drawing up a model form of annual report, as has already been done in the case of medical officers of health.

British Medical Journal.

SATURDAY, AUGUST 1st, 1925

THE BATH MEETING

ALL who were fortunate enough to attend the Annual Meeting of the British Medical Association at Bath are agreed that from beginning to end and in every respect it was one of the most successful that has ever been held, and this notwithstanding the enforced absence, through illness, of the President (Dr I. G. Thomson), who had entered heart and soul into all the arrangements. Though unable to take his part in the week's proceedings, Dr Thomson had the satisfaction of knowing that the Acting President, his friend Mr W. G. Mumford (who with Dr R. G. Gordon had shared with him the chief labours of organization beforehand), was worthily upholding the traditions of Bath as a medical centre and as a city famous for its hospitality. Placed by a sudden stroke of fate in the middle limelight of a great public event, Mr Mumford rose to the occasion with untiring devotion and conspicuous grace. The unanimous choice of his colleagues was thus abundantly justified, and the ninety-third Annual Meeting of the British Medical Association proceeded smoothly in an atmosphere of the utmost good fellowship and friendly enjoyment. If only from the point of view of numbers, the meeting must be judged a great success, for by luncheon time on Wednesday more than 1,000 names had been registered, and by Friday this total was exceeded.

The scientific and clinical work of the meeting was carried out, as at Bradford last year, in twelve Sections—a manageable number tending to the concentration of interest. Many of the papers and discussions ranged over matters of much importance in everyday practice. The practical nature of the sectional programmes will be gathered from the summaries printed elsewhere in the present issue, and it was fitting that some of the debates should have been planned with a special eye to those diseases with whose treatment Bath is traditionally associated—for example, rheumatoid arthritis and hyperpiesia, discussed by the Section of Medicine, insomnia by the Neurological Section, and chronic arthritis by the Section of Therapeutics. A combined discussion between the Sections of Surgery and Orthopaedics on the treatment of fractures, with special reference to its organization and teaching, was one of the features of the meeting, and another subject of great importance—rheumatic infection in childhood: its early diagnosis and prevention—was debated jointly by the Sections of Public Medicine and Diseases of Children. The circumstance that the first morning session of the Pathological Section (reported in full at page 189) had been allocated to a discussion on filter passing viruses, gave members working in many departments of medicine an early opportunity of hearing some account from their own lips of the recent investigations of Dr Gye and Dr Murray Gordon, and of the technical achievements of Mr Barnard. Supplementary to the main work of the Sections there was a well planned pathological museum on an upper floor in the Technical College the specimens there shown and the demonstrations there given added considerably to the scientific value of the Bath meeting.

Before the Sections began to meet four days had,

as usual, been spent by the Representative Body of the Association in the transaction of medico-political business and the discussion of such internal affairs as finance, organization and administration. A full report of the proceedings of the first two days appeared in last week's *STANDARD*, and the conclusion of the Annual Representative Meeting is recorded in this issue. From these accounts and from the short informal notes printed in the *JOURNAL* under the heading of *Annual Meeting Notes*, it will be seen that each of the four days was fully occupied and that while many matters of professional importance came under review and opinion here and there (notably on the question of individual medical defence) was sharply divided, the debates proceeded on the whole with urbanity. This may have been due to the relatively quiet nature of the business before the meeting or perhaps to a growing mellowness of temper, but whatever the reason it may faithfully be said of the Chairman, Dr Brackenbury, that he handled his first Representative Meeting with that combination of firmness, vigilance and tact without which the conduct of public business in a limited time is impossible.

Before closing this brief note on the work of the Representative Body we would like to mention a few striking figures which came to mind when the Treasurer presented his financial statement and the Chairman of the Organization Committee spoke of the remarkable growth in membership. At the Annual Meeting held in Bath in 1848 there were fewer than 1,800 members, and the income of the Association was barely £1,400 when the Association met again in Bath in 1878 the membership was 7,500 and the income £11,500; the membership has now reached 29,680, and the current financial report shows an income of £122,840. In 1878 Dr Jackson, in his Presidential Address, spoke of the strides made by the Association during the thirty years that had passed since the previous meeting at Bath, and in particular pointed with pride to the fact that a Colonial Branch had just come into existence. Since 1878 there have been added to the Jamaica Branch no fewer than fifty-two Branches of the Association overseas and in the past fortnight many of these have sent delegates to the Royal Opening at Tavistock Square and to the Annual Meeting at Bath, some bearing gifts for the parent body's new house, and all bringing messages of loyalty, affection, and good will.

For the social side of the Bath meeting no praise could be too high. Hospitality was showered upon the guests in princely abundance, every afternoon had its programme of excursions and amusements, and every evening at least one brilliant function. Such entertainments do not fall like manna from the sky, nor can they be improvised in a few days or weeks; their success is the outcome of infinite care and whole-hearted generosity. Among the many who worked to this end with the leaders of the local profession, one or two must be named. Alderman Cedric Chivers, who accepted again the office of Mayor for the year of this meeting, devoted himself day and night to the comfort and pleasure of the city's guests. From the moment of his visit to the Representative Body on July 17th until the closing day (and, it might truly be said, for many months beforehand) the Mayor seemed to have but one wish—to ensure the success of this medical meeting. His generosity reached its acme on the evening of his reception in the Grand Pump Room and its precincts, when, in company with the Mayoress Madame Sarah Gird, he received some 2,500 guests. Tributes to the hospitality of Alderman

CHURCH, to the tireless and self-effacing work of Mr John Hutton, Director of the Hot Mineral Baths, and to the friendly interest of the Lord Lieutenant of Somerset, the Marquess of Bath, will be found in our report of the Annual Dinner. We would only add that in his graceful words about the beauties and healing virtues of Bath and the hospitality of its citizens, Lord Dawson spoke for all who shared with him in the delights of the Annual Meeting of 1925.

RELIGION, SCIENCE, AND SUPERSTITION

THE Bishop of Birmingham's sermon at the service at Bath Abbey on July 21st will be memorable. Dr Barnes is a man of science and emphasized the fact by wearing in the pulpit the academic gown of a Doctor of Science. He is a Fellow of the Royal Society and won that coveted distinction by his contributions to mathematical science. It would serve no good purpose to attempt to paraphrase his sermon, the report at page 225 should be read—it is not long. It will be found to contain one of the most pregnant utterances which the British Medical Association has heard or read for many a day. It was so because, leaving aside all the banal stuff about the conflict between religion and science, he went to the root of the matter and put into words what many of us have vaguely felt. This is that both are suffering from the same movement or tendency, which for the one shows itself in the recrudescence of thinly disguised magic in worship, and for the other in 'faith healers, osteopaths, and children psychoanalysts'. Both medicine and science are in fact, subject to the same pressure of irrational belief. This conclusion will not be disputed by us: the explanation he suggests is that the scientific temper which trusts to reason is a recent acquisition of humanity, so that its place in our mental make up is as yet insecure: therefore the critical faculty is easily inhibited. There are thousands of educated people—educated up to the standard of the public school and university—and some dozens at least of well known men of science who boast that this is so with them. Superstition—that is, belief that does not rest on a basis of accurate investigation—is the bane of medicine, and threatens religion.

We are forced, then, to consider the very serious question Dr Barnes raised. We are accustomed to speak glibly of the progress of science, but can we confidently assume that the influence of science and scientific methods on the public mind will continue to increase? We are forced, indeed, to ask whether we can preserve what we have won. There is, to make no hesitate the fact that Graeco-Roman civilization was finally ruined by the intellectual degeneration with which the peoples of Europe became afflicted with that civilization disappeared nearly all that the Greek school of science had won for medicine.

Though during the last century accurate clinical observation and patient research had caused medical science first to reach, and then to surpass the level of the great age of Greece, we have the Bishop sad to ask whether 'an understanding of its value is safely rooted in popular esteem. The great triumphs of Greek medicine were gradually lost and medicine ceased to be scientific as it was slowly brainized by the new vitality acquired by folk beliefs. Old wives lost magical charms, visits to healing shrines—all the paraphernalia of primitive health cults—renewed their ascendancy and the recrudescence of magic and superstition which infected medicine found expression also in religious extravagance.

There are not wanting signs that something of the same kind may happen again. It will be said that the modern world will not lightly discard the material advantages chemistry and engineering science have placed at its disposal, but medicine is in a rather different position, and we already see not a few members of the public—not necessarily the most uneducated—resorting once more to what is little better than magic and witchcraft. It will not do to be overconfident.

The strange trial in Tennessee about which public opinion in America has been worked up to an extraordinary pitch of excitement is evidence that the battle for freedom in thought is not won. In Tennessee, and we believe in all other of the American States, the teaching of religion in the public schools and the State universities is forbidden by law. It has proved not difficult to lead the people of Tennessee to believe that the teaching of the doctrine of evolution is anti-religious, and they have therefore easily accepted the view that to teach evolution in the schools while the teaching of religion is forbidden is not fair. Accordingly Tennessee adopted a law forbidding any teacher in a school wholly or partially supported out of State funds to teach any theory which denies the story of the Divine creation of man as taught in the Bible, and to teach instead that man has descended from a lower order of animals. The defendant was indicted for unlawfully and wilfully teaching in a school supported by public funds certain theories denying the story of the Divine creation of man as taught in the Bible, and instead teaching that man was descended from a lower order of animals. After the court had held that the Tennessee Act did not violate the constitution either of the United States or of Tennessee, the result appeared to the onlooker to be irrefutable, and the verdict did in fact go against the defendant, who was fined 100 dollars. Notice of appeal to the Supreme Court of Tennessee was given, and it has been assumed by many writers in America that if this court refuses to reverse the verdict there will be an appeal to the Supreme Court of the United States. It seems, however, by no means certain that the constitution of the United States renders this possible. If not, there would then remain only an amendment of the constitution, and for this thirty-six of the forty-eight States would have to agree. So far from this being probable Mr W. J. Bryan, who made himself the leader of the fundamentalists, believed that he might succeed in bringing a sufficient number of States to the opposite opinion, and already, it is reported, bills similar to the Tennessee statute have been introduced into several State legislatures. Mr Bryan's sudden death immediately after the trial in the first Tennessee court may possibly diminish the impetus of the movement he was guiding, but there is talk of introducing a bill modelled on the Tennessee statute into the Federal Congress, and in this way the controversy might be kept alive, whatever the final decision in Tennessee may be. If this happens it may very well drag on for years and the issue is uncertain.

Dr Barnes while giving his warning of the gloomy possibilities the future contains is still optimistic. After recalling the historical fact that in the thought and conduct of men progress and reaction alternate, he did not hesitate to add: 'After all, man is a reasoning animal and therefore in the long run reason will prevail. But it may be a very long run. Meanwhile the medical profession will welcome so closely reasoned a review of the situation as was presented to us by the Bishop of Birmingham in his sermon to the British Medical Association this year.'

ANNUAL MEETING NOTES

THE POPULAR LECTURE

Sir William H. Bragg on the Carbon Atom

A very large audience, lay and medical, gathered at the Palace Theatre, Bath, on Friday evening, when Sir William H. Bragg, KBE, FRS, delivered the Popular Lecture. His subject, illustrated by lantern views and some fascinating experiments with soap bubbles, was "The carbon atom as seen in organic structures by x rays." Mr. Wilfrid Mumford, FRC S, Acting President, was in the chair. Sir William Bragg said that the world was constructed of some ninety kinds of atoms assembled in molecules of innumerable sorts, just as the limited number of letters of the alphabet were combined to form an infinite variety of words. Some atoms were much more common than others, oxygen, for instance, made up half the known world, and silicon half the remainder. Compared with these the carbon atom was rare—only about 1/700 part of the world was made of carbon—but it was a very important constituent of living organisms and slipped to a very large extent the processes of life. Two well known substances made of carbon were the diamond and black lead. These substances, as the x rays had proved, differed only in the way in which their atoms were arranged. The accident of atomic arrangement alone separated the most brilliant and precious thing in nature from the most dull, commonplace, and unconsidered. The world of matter thus depended not merely upon the choice of atoms but of arrangements of atoms. The molecules of organic substances contained other kinds of atoms as well, generally oxygen, hydrogen, and nitrogen. Most of the atoms were built on to two different designs. One design was based on the construction of these atoms into a ring—the famous benzene ring—which was the unit of construction of dyes, explosives, many drugs, and other well known substances. Upon this ring and its combinations some of the greatest industries depended. The other was a chain of carbon atoms which might have any length, and which was fringed along its sides by hydrogen atoms and finished off at either end by terminal groups of atoms of various kinds. If the ends as well as the sides were of oxygen the result was a paraffin, the addition of oxygen at one end made an alcohol, when this was exchanged for a slightly more complicated grouping of atoms the result was a fat, a soap, or an oil. The shape, design, and arrangement of a molecule, therefore, were of first-rate importance. A certain complicated molecule, for example, containing several benzene rings, furnished the colour of the rose, and a very small change in the design converted the molecule into the colouring matter of the cornflower. The long molecules that formed the oils and soaps tended to spread quickly and thinly over a watery surface because the special group which terminated one end of the chain had an affinity for water and rooted itself therein. The molecules of oil, thrown on water, spread all over it, and stood upright, like corn in the field, so did the long molecules of soap in a soap solution. Both inside and out the soap bubble was lined with layers which not only held it together but also gave it a slippery surface. The delicate colours of the soap bubble were due to the extreme thinness of the film, and, in fact, the degree of thinness was estimated by the absorption of the colours. He showed some lovely experiments illustrating the gradation of colours in the soap bubble as the film thinned, how at first the cruder bands of colour appeared, and then—each different thickness having its own colour—how these were succeeded by the rich purples and other colours until finally the black spot appeared which presaged the bursting of the film. It was estimated that where the purple appeared in the soap bubble the thickness of film was a 250 millionth of an inch, and that at the black spot the thickness was one-fiftieth

even of this, indeed, at the black spot in the soap bubble only a double row of molecules remained. In showing the lines of the bubble and its sensitiveness even to the clapping of hands of the audience, Sir William Bragg remarked that no one could have a proper theory of life until he had some understanding of the soap bubble. He went on to show how when grease was spread on a surface the molecules formed themselves into layers like pile carpets laid one upon another. Water would not wet a glass that was, even in the scientific sense of the term, dirty, because such glass was covered with a thin film of grease, otherwise glass particles would attract the water particles and the glass be thoroughly wetted. The fact that water would wet some substances and not others—it would not wet substances with pure hydrogen terminations, for instance—was really at the basis of the new method of separating ores. Finally the lecturer alluded to the new light which had been thrown on all these investigations into molecular structure by spectroscopic study with the x rays. These rays themselves a light ten thousand times more delicate than ordinary light, had provided a means of measuring wavelengths directly and far more accurately than before. The chemist was thereby helped to estimate the actual positions and dispositions of atoms, and the length of a molecule, which might be a 10 millionth of an inch. A new vision so keen and delicate as that afforded by the x rays might be expected to be of great assistance in understanding the form and behaviour of these molecules. These molecules of various shapes and forms were at the bottom of all structure, and as chemistry has hitherto thriven on the endeavours of chemists to elucidate these matters by the old methods it might be hoped that with the new weapon of the x rays fresh fields of knowledge would be opened up. These molecules were at the bottom of all structure, they played a great part in the processes of life, and an understanding of them would bring us nearer to an appreciation of the workmanship of the human body, which was part of the general pattern of organic structure. Sir Percy Stothert proposed a vote of thanks for an enthralling lecture, this was seconded by Dr. Alfred Cox, who said that the romance of the subject must have appealed even to those to whom its science was a closed book.

THE PATHOLOGICAL MUSEUM

An extensive collection of museum specimens and microscopic preparations was assembled in the Pathological Museum. The museum, opened by the President on July 21st, was arranged in the Chemical Laboratory of the Municipal Technical College, in a well lit room where the numerous exhibits were displayed to advantage. In arranging the museum the committee followed the anatomical plan of grouping together the exhibits as far as possible according to the different systems of the body. Thus, on entering the museum, the visitor found collected in Section A ten exhibits illustrating diseases of the circulatory system. Most of the specimens in this section were sent from the museum of the General Hospital, Bristol, and were prepared and annotated by Dr. Carey I. Coombs and Dr. Geoffrey Hadfield. They illustrated the more common varieties of cardiac disease by means of museum specimens, photomicrographs, drawings, and electro-cardiograms. The first exhibit of specimens and photomicrographs, illustrating the histopathological evolution of cardiac rheumatism, attracted considerable attention. The specimens were arranged in a series displaying the evolution of the disease from the initial pancarditis, characterized by a specific myocardial lesion, to the late stages of the disease, the result of repeated and prolonged infection and reinfection. A separate series of exhibits illustrated the histopathology of the subcutaneous nodule of acute rheumatic infection. Included in this series was

a demonstration of the recent research of Cortes and Thomas, who have shown that careful examination will reveal the presence of such nodules in the majority of albuminuric children. Amongst the specimens and microphotographs illustrating some features in the pathology of chronic infective endocarditis were collected specimens which demonstrated the liability of congenitally defective and previously damaged hearts to infection by oral and faecal streptococci, the mode of invasion of the endocardium, a type of endocarditis occurring in pigs following the chronic bacteraemia of some erysipelas, and fatal heart-block in two cases of endocarditis lenta, in which the infection involved the pars conchinnacea septi.

Section B contained three specimens illustrating respiratory diseases. Amongst the fourteen exhibits of Section C devoted to the digestive system, Dr G. Hadfield showed a series of microphotographs from a case of pancreatic atrophy in a child, reproducing the lesion found in animals after experimental ligation of the duct and not accompanied by glycosuria, designed to illustrate the independence of the glandular tissue and the cell islets of Langerhans. Eleven exhibits of diseases of the genito-urinary system were assembled in Section D. Section E (ductless glands) contained a series of about fifty specimens accompanied by microphotographs, diagrams, and microscopic preparations illustrating the anatomy, physiology, and pathology of the thyroid gland. These illustrated work carried out in the Dunn Laboratories, St. Bartholomew's Hospital by Dr. Scott Williamson and Dr. Innes Pearce. Section F contained four exhibits of disease of the nervous system, Section G eleven exhibits of diseases of bones and joints, and Section H a number of tumours and unclassified specimens. A unique feature of the museum was found in the laryngological section (Section J), which contained a collection of about 250 foreign bodies removed from or found post mortem in the upper respiratory passages. This collection had been assembled to illustrate the discussion in the Laryngological Section on bronchoscopy and oesophagoscopy. Next by were a number of specimens lent by Mr. V. E. Negus, illustrative of evolutionary factors in the causation of pharyngeal diverticula. The museum contained also four special exhibits. The first of these was an exhibit from the Institute of Anatomy, University College, London. Here were displayed a number of anatomical specimens cleared by the Spitzholz method and stereoscopic photographs of embryos and a number of other anatomical preparations. A second special exhibit was a collection from the Wellcome Historical Medical Museum to illustrate the historical evolution of spectacles. A third was a series of plates and books showing the technical process by which reproductions in colour are prepared from pathological specimens. A fourth, an old operation lantern, circa 1766, lent from the General Infirmary, Salisbury, by Dr. L. S. Luckham.

Each afternoon demonstrations were given in the museum in accordance with the following programme.—*Tuesday* Dr. G. Hadfield, diseases of the pulmonary artery, Mr. M. Crichtley, Kufs's reaction in the cerebro-spinal fluid, Dr. Bayon, some unusual neoplasms. *Wednesday* Dr. C. F. Coombs and Dr. G. Hadfield, pathology of cardiac infection, Dr. Hadfield, specimens of pancreatic disease. *Thursday* Dr. G. Scott Williamson and Dr. Innes Pearce, the thyroid gland, Dr. G. Hadfield, hepatocellular degeneration. *Friday* Dr. G. Scott Williamson and Dr. Innes Pearce, experimental gastric ulcer, Dr. C. F. Coombs, rheumatic heart disease.

THE REPRESENTATIVE MEETING

In the SUPPLEMENT this week we conclude publication of the full report of the Annual Representative Meeting at Bath. The short notes printed below are intended to give

an outline of the course of the discussions on Monday and Tuesday, July 20th and 21st.

The greater part of Monday's session was devoted to the reports of the Medico-Political and Public Health Committees, and the matters under review were of obvious importance. The debate on the revised policy on coroners' law and death certification and registration might, perhaps, have been shortened and simplified if a clearer view had been obtained of the real objects of the revising subcommittee, and the reason for the modifications recommended. The chief amendment, that put forward by Maylebone, would have involved a return to the existing policy of the Association, as opposed to modifications adopted by the subcommittee, after protracted discussion, on grounds of expediency. The point at issue was one of substance, but some misapprehension seemed to arise. Sir Jenner Veinall, however, was able to put the matter straight, and the risk of abandoning the confidential scientific certification, whether explicitly or by the indirect method of making the confidential report optional, was averted. The rest of the debate turned on questions of remuneration or of detail, and Dr. Hawthorne and Dr. Mothesole contributed some useful verbal amendments. On the whole the judgement of the revising subcommittee was fully vindicated, though it may be doubted whether its full import was grasped by all. Possibly the amendment by North-East Essex might have been discussed and adopted had it been moved otherwise than formally from the chair. The failure to amend the paragraph of the report dealing with the issue of supplementary death certificates, after considerable discussion, illustrated the usual difficulty of giving adequate expression to principles on which the great majority were in cordial agreement from the outset.

The decision of the Council against taking any steps to obtain a larger number of direct representatives on the General Medical Council was supported by a sufficient majority (84 to 53), though that majority was possibly due rather to appreciation of the general indifference of the profession on this point than to motives of policy, and Dr. Scott put the Willesden amendment with considerable force. The discussion on the amendment in connexion with payment for health certificates for elementary school children served to inform representatives of the local practice in well organized areas, and the action taken was a useful example of constitutional procedure for the rectification of initial mistakes.

For the rest, the only substantial amendment adopted was the Manchester motion to refer back the portion of the report on factory medical service dealing with the transfer of administration of the work of occupational hygiene to local authorities, and the provision for a complete service. The adoption of the remainder of the report marks a distinct step in the development of a policy to meet changing industrial conditions. It was unfortunate that so important and controversial a matter as the report or the Committee on Drug Addiction should have come forward so late as Monday morning. In these circumstances the discussion was necessarily inadequate, and it was left to Dr. Bone to put forward the most controversial point of all as a personal motion, he had an extraordinarily difficult task manfully carried through, in explaining not only the somewhat anomalous position created by the necessity of tendering evidence to the departmental committee in advance of the Council's approval of that evidence, but also the issues involved in his motion for empowering a special medical tribunal to advise the Home Office as to restricting the right of registered medical practitioners to prescribe dangerous drugs in certain circumstances. It was a wise suggestion on the part of Dr. McCutcheon to defer the final vote on this

point until the representatives should have had the opportunity of considering a written report.

Of the more important motions from Divisions, that from St. Helens and Warrington on unqualified practice was dealt with on sound lines on Dr. Hawthorne's lead, while the Brighton motion on the question of registration of nursing homes, as elucidated by the general discussion and expanded by Mr. Bishop Huxman, may be a useful weapon in the near future. The presentation of a going to the Representative Body by Dr. C. J. Marsh, representative of the West Dorset Division, helped to expedite proceedings which had already proved unexpectedly protracted.

On the Public Health and Poor Law Report two matters of major importance and several of considerable interest came under discussion. Of these the first—namely, the approval of the amended scale of salaries for public health appointments—was in the hands of the Chairman of Council. The withdrawal of the several amendments, except that from North Glamorgan and Brecknock, and the lines followed by the discussion prior to the adoption of the scale, showed the measure of the support secured in the course of some five years' laborious work and delicate negotiations conducted under Dr. Bolam's leadership. It was clear from the debate that, with a full appreciation of the hard cases which occur, and all the difficulties involved in loyal adherence to the scale, the representatives were now prepared to endorse his policy without reservation, in confident anticipation of its final success. The second point for notice was the cordial approval of the four recommendations of Council in respect of the use of preservatives in food. Whatever the obvious deficiencies of the preamble to the report considered by the Council that morning, it was clear that the representatives endorsed to the full the policy of restriction set out and the statement of its importance in the interests of public health. The Hendon motion for the standardization of calf vaccine lymph referred to Council without opposition, showed that the Divisions, even the most recently organized, are not prepared to leave measures for the protection of public health entirely to the initiative of the Council. The session closed with Dr. Hawthorne's introduction of the report on medical benevolence procedure, which tended to seem more adequate discussion of the subject than would have been likely had this statement been debated the same evening.

Tuesday's agenda was unexpectedly heavy. After three days devoted to the less controversial reports the representatives were faced with the necessity of dealing with the dangerous drugs question, the medical benevolence question, the Dominions Report, the Naval and Military Report, and the Hospitals Report, between 10.30 a.m. and 4.30 p.m., with an interval between those hours for the statutory Annual General Meeting of the Association. Accordingly a meeting which had begun by enjoying protracted discussions on uncontroversial matters dealt with a number of controversial points with unexpected vigour and dispatch. There could be no doubt that Dr. Waller's vigorous attack on the administration and policy of existing medical charities, and his contention in favour of a medical benevolence scheme to be conducted by the Association as a benefit for its own members, expressed the feeling of a considerable section of the membership. It was equally clear that when Dr. Daviden, with the weight of Manchester behind him, and speaking as the prime supporter of the demand for reform put forward at Portsmouth and Bradford, lent cordial assent to the Council's scheme that scheme would be accepted. By the unopposed nomination of Dr. Waite to the new committee, the zeal and sincerity of the leader of the opposition were by a happy stroke secured for the scheme. On the report of the Dominions Committee, in spite of the need for dispatch, time was found to welcome the overseas delegates' appreciation of

the work of the Association. That some men in England, as elsewhere, in the words of Dr. Roberts in "get up and talk piffle" men have established another bond of sympathy between the parent Association and its overseas branches. That the work of the parent Association is effective overseas as well as in the United Kingdom is best demonstrated by personal testimony of the overseas representatives. There was no difference of opinion as to either the gravity or the necessity of the action recommended by the Council in respect of the situation in the R.A.M.C., and further reference to this is made elsewhere.

In presenting the report of the Hospitals Committee, Mr. Souttar was greeted with a warmth which testified to the regret of the Representative Body for its oversight in failing to re-elect him to the Council on Saturday. That the repentance was to be fruitful for the future was subsequently shown on Dr. Jaggle's motion for the amendment of procedure. Mr. Souttar at least had the satisfaction of securing the two-thirds majority necessary to leave the hospitals policy of the Association a complete and logical statement, a sufficient instrument for the scheme of gradual education of the profession and the public already projected. The debate showed outstanding differences as to matters of fact and of sentiment. It showed also a progress, definite if slow, towards unanimity. The attitude of Birmingham in proposing compromise and modification rather than rejection was significant. The matter was eventually referred to the Council for consideration.

SECRETARIES' CONFERENCE

The Secretaries' Conference on Wednesday met under conditions which might well have rendered any conference futile, for it was held on the hottest day of the meeting in the hottest room in Bath, and many secretaries had already done four days' work as representatives. Moreover, the function of this particular body is to confer rather than to take definite decisions on points of policy or methods of action, and the atmosphere in which it meets is therefore of particular importance. In spite of difficulties it was a successful meeting. It was well attended, and its members showed a lively appreciation of the opportunity it offered for a comparison of experience and mutual encouragement. The opening papers by Dr. Brown of Sheffield and Dr. Buchan of Lewisham were cordially received and showed a record of good work which should encourage less experienced workers for the Association. The general discussion of propaganda showed that many views are finding the appointment of special local propaganda committees an effective stimulus to organization, that on medical benevolence augured well for the future of the new committee provided for by the resolution of the Representative Body on the Medical Charities Report earlier in the week. The important question of medical golf was raised by Dr. Anderson, and received the careful consideration undoubtedly its due, before it was remitted to the care of the new committee, to which the conference elected Dr. McCutcheon, Dr. Kirk, and Dr. Le Fleming. The outstanding features of the meeting were the unusual absence of criticism of the central office, illustrated by the gentleness with which the usually vexed questions of notification of resignations and non-member lists were handled, and the discussion of the relationship of the Association to other medical organizations, more particularly to local medical societies and Local Medical and Panel Committees. The debate on the latter point opened by Mr. Russell Coombe showed that the majority of the secretaries fully realized the difficulties and even the real danger of the position, and Dr. Blackburn's warning did not fall on deaf ears. It showed also that adequate steps can be taken, and in many cases have already been taken, to deal with that position. The only definite expression of dissatisfaction with the

general conduct of the Association's affairs came from Dr Parry, and it was clear that his misapprehension as to the relationship between the Council, the representatives, and the Divisions was by no means general, although the conference fully sympathized with his contention as to the desirability of initiative in the Divisions on questions of policy. In general the impression left by the conference might be summed up in Dr Willer's remark early in the afternoon, to the effect that successful propaganda is largely a question of the personality of the local executive, and more especially of the honorary secretary. If this is a fair statement of the position, the conference showed grounds for full confidence in the future. That the business was conducted with such dispatch must be attributed to the able chairmanship of Dr Mun Smith, and the general habit of mind which enables an Association secretary to do two hours' work in one.

THE BATHING ESTABLISHMENT

On each day of the meeting the bathing establishment was thrown open for inspection, and several hundreds of the members availed themselves of the opportunity of seeing how modern are the uses which Bath makes of its waters. The visitors were conducted round the baths by Mr John Hatton, the director, or by the million or other members of the staff, and the various treatments were carefully explained. Models were hired—it may be taken for granted that no one supposed them to be actual patients—on whom the applications were demonstrated for the visitors' benefit. The principal part of the bathing establishment consists of three buildings in close proximity—the Old and New Royal Baths, and the Queen's Baths. The New Royal Baths were entirely rebuilt in 1916, and have had some wings added since. The Queen's Baths were opened in 1889. The Old Royal Baths are being converted into a suite for the Plombières treatment, and this will enable certain rooms in the newer establishment to be released for vapour treatment, which is at present being given on the lower floor of the Queen's Baths. It would be tedious to recite all the varied forms of baths, douches, sprays, and inhalations which the visitors saw administered. The immersion baths, for instance, include deep baths, in which the patients are subjected to varying temperatures under considerable pressure of water, and reclining baths, with less pressure. These deep and reclining baths are the oldest forms of the Bath cure, upon these treatments the reputation of Bath was first founded, and they are still its peculiar speciality. Then there are the Bouillon-Lancy baths, with a submerged fan douche, the Nauheim baths, in which carbon dioxide is liberated in a nascent form, and the whirlpool baths, in which a rapid circulating movement of the water is made. The Air and Vichy douches, with massage, are well known, streams of water are directed on to the patient, who sits in a chair in the Air system, or lies on a padded table in the Vichy. The Scottish douche is also a feature of this department, jets are directed at high pressure from two hose pipes, and a hyperthermic application (104° to 112° F) for a few minutes is followed by a cold application for as many seconds. Other treatments consist of vapour baths, hot-packs, mud packs, needle sprays, and so forth. There are two large swimming baths in which the water from the hot springs (rising at 117° to 120° F) is cooled to about 84°. These warm swimming baths have been found useful for encouraging and re-educating movement in patients suffering from forms of chronic arthritis. A visit was paid to the department of electrotherapy, which has all the approved light and heat treatments, including radiant heat by the Greville and the Dowson systems, ionization, diathermy, and high frequency. The most recent addition

here is a room for general ultra-violet irradiation. Adjoining the Royal Baths is a department of mechanotherapy—described by someone as having the appearance of a cross between a gymnasium and a torture chamber—where machines on the Zander (Swedish) principle are used for inducing passive or active movements. The Pump Room, where the waters are available for internal use, was largely given over during the week to the meetings of the Association. Many of the visitors also went to the Royal Mineral Water Hospital, a few hundred yards away from the bathing establishment, where there are departments of medical hydrology and other forms of physiotherapy, as well as a school of massage. Altogether the modern bathing establishment, which is estimated at a capital value of well over £200,000, does not lose by comparison with the adjacent Roman Thermae, although the latter may have or may have had greater architectural glories. In decorative skill, in regard for the nuances of spa treatment, the Romans can hardly have beaten the baths committee of the present city council. One has only to look at the appropriate colourings of the walls, the tessellated pavements, and the ceilings of some of the chambers which have a delicate suggestion of sky, with cloud and sun, to realize how subtle are some of the factors which enter into balneotherapy. A medical handbook to the bathing establishment, compiled originally for the Bath Division of the British Medical Association, is handed to every visitor. Lastly, we should mention the pleasure and refreshment which many of those attending the meeting obtained from morning and afternoon baths in one or other of the excellent thermal swimming baths referred to above.

MEMORIAL TO "PARRY OF BATH"

One of the minor events of the Annual Meeting at Bath was the unveiling at No. 27, The Circus (next door to the house of the President, Dr Thomson), of a memorial tablet to Caleb Hillier Parry, M.D., F.R.S., of whom a brief eulogium appeared in the President's Address in the last issue, together with a portrait (pp. 155-56). Parry was born in 1755 and died in 1822, after practising in Bath for thirty-six years. A large company assembled around the doorway of the house he occupied in The Circus, including some members of the Parry family, one of whom was the Most Rev. Dr Oswald Parry, Archbishop of the Province of the West Indies. The Mayor of Bath called upon Sir Humphry Rolleston to unveil the tablet, and Sir Humphry, having done so, gave a brief account of this ununsided and distinguished man. Parry, he said, was the son of a literary divine and the father of Sir William Edward Parry, the Arctic explorer, and of Charles Henry Parry, another noteworthy figure in Bath medicine. Like so many men distinguished in after-life, he was President of the Medical Society of Edinburgh. In 1779 he settled down in Bath, and hardly ever left it even for a day. He was a life-long friend of Edward Jenner, who dedicated to him his famous 'Inquiry into the causes and effects of the variolæ vaccine, a disease discovered in some parts of the western counties of England, particularly Gloucestershire, and known by the name of the cowpox' (1790). Both these men were active members of a small medical society in Gloucestershire and were much interested in the morbid anatomy of angina pectoris, on which, in 1799, Parry published "An inquiry into the symptoms and causes of the syncope anginosa, commonly called angina pectoris, illustrated by dissection." Sir Humphry Rolleston went on to say that though it would appear appropriate and, from their common friendship with Jenner, not improbable that Parry should have attended John Hunter when in Bath, there was no evidence to confirm this anticipation. Parry was one of the first to observe the disease

exophthalmic goitre now commonly called Graves's disease, but, to quote the late Sir William Osler, who spoke of it as "Pari's disease," if any man's name was to be thus associated "undoubtedly it should be that of the distinguished old Bath physician" Pari's broad outlook on life was reflected in his activities, he wrote much and wrote well on many branches of medicine, as an experimental physiologist he investigated the mechanism of the circulation, he was a geologist, and also did pioneer work in agriculture, especially by proving that the valuable merino sheep could be bred as well in this country as abroad. Struck down by paralysis and loss of speech in October, 1816, six years before his death, he bore this affliction with wonderful fortitude and continued to work, though unable to carry on his medical practice. This was not the least of the many lessons that might be learnt from this great man—Pari of Bath. Dr. Rupert Waterhouse, another medical tenant of the famous Circus, proposed a vote of thanks to Sir Humphry Rolleston, and made many complimentary references to his distinctions and qualities, and especially to the esteem in which he was held by the medical profession at large. Alderman Preston King, M.D., seconded the vote of thanks, with some humorous comments at the expense of Bristol, whose university the previous day had done Sir Humphry Rolleston honour. Bath, he said, was the more ancient city, and there was a time when the postal address of Bristol was "near Bath." Archbishop Pari, who said that although he had been twenty-five years in the West Indies, until lately as Bishop of Grenada, he always regarded himself as a Bath citizen, associated himself on behalf of the Pari family with the vote of thanks.

ORTHOPAEDIC HOSPITALS

At the close of the joint meeting with the Section of Surgery on Friday, July 24th, the members of the Orthopaedic Section were entertained at the Grand Pump Room Hotel to lunch, on the invitation of Mr. W. G. Mumford, I.R.C.S., and were afterwards conveyed in motor cars to Combe Park, on a visit to the Ministry of Pensions and the Children's Orthopaedic Hospitals. A number of interesting cases were demonstrated by Mr. Hey Groves, Dr. Forrester-Brown, and others, and the company then enjoyed tea and refreshments in the grounds of the Children's Hospital, where they were the guests of Lady Stothert. The buildings of this hospital were inspected with great interest under the guidance of Mr. Walter Mallett of Bath, to whose energy and financial aid they largely owe their existence. The huge open ward for seventy-six beds, built of reinforced concrete, glass, and asbestos, impressed the visitors with its lightness and probable durability. The administrative buildings in brick and Bath stone are not yet completed. The cost we understand to have been remarkably low.

THE OFFICIAL RELIGIOUS SERVICE

The Abbey Church, Bath, was crowded in every part for the special service on Tuesday afternoon, July 21st, when the preacher was the Lord Bishop of Birmingham (the Right Rev. E. W. Barnes, Se.D., F.R.S.). The service was conducted by the Venerable the Archdeacon of Bath. The members of the Association assembled at the Guildhall, where they robed, and then walked in procession to the Abbey, headed by a civic procession which was led by the Mayor (Alderman Cedric Chivers) and the Marquess of Bath (Lord Lieutenant of Somerset). "Let all mortal flesh keep silence" (Gustav Holst) was rendered as an anthem. The Bishop of Birmingham's striking sermon is printed in full on another page this week.

CONDITIONS IN THE R A M C

In October, 1919,¹ and again in April of this year, we commented on the unfavourable manner in which majors in the Royal Army Medical Corps had been treated in regard to their pensions under the Royal Warrant of 1919. We might have been pardoned for assuming that such obvious blunders as were perpetrated in that Warrant merely required that attention should be called to them to bring about their rectification, but more than five years have now passed since the attention of the War Office was called to the matter, and the trouble still remains. The British Medical Association has for years been doing its utmost to obtain reforms which will restore the Corps to its former popularity, and it was only after a long series of disappointments that it decided upon the serious step which was taken at the Annual Representative Meeting last week at Bath—namely, the passing of the following resolution: "That inasmuch as the provision for a 20 per cent reduction in retired pay of majors after twenty years' service under the 1919 Warrant can have the effect of reducing the pensions of many of these officers below the sum of £1 per diem which was provided by the Warrant under which they joined the Service, the Representative Body is of opinion that a serious breach of faith has been committed by the Government, and that therefore the Association is unable to recommend recently qualified doctors to enter the R A M C, and declines to publish the terms and conditions of service in the R A M C in the Educational Number of the British Medical Journal or in its other publications until the Council is assured that this and other matters under negotiation have been settled to its satisfaction." It would be as well for the profession and the public to understand that, although the question of the majors' pensions precipitated the crisis, it was by no means the only source of dissatisfaction. There are several other questions in regard to pay and promotion which have contributed in no small measure to the present serious dearth of candidates for commissions in the R A M C. The Association has viewed with feelings akin to dismay the fact that the Corps has almost entirely ceased to attract young graduates of the right class, and year after year it has urged upon the War Office and the Army Council the urgent necessity for action. The country will not have forgotten the magnificent work during the war of the R A M C, strengthened as it was by a considerable proportion of the civil profession, and it is by no means in the interests of doctors alone that the Association has been driven to adopt as a last resource a method of procedure which is profoundly distasteful to it.

VICTORIA PARK HOSPITAL

In *The Story of a City Hospital* Lady Butterworth has told very pleasantly the history of the foundation and progress of this useful institution, which, beginning in 1848 as a dispensary in Liverpool Street, E.C., soon developed into the well known hospital in the Bethnal Green district. In 1849—three quarters of a century ago—the four acres of "Bonnet's Fields" which the committee acquired was suburban or nearly rural, a fact that is realized with difficulty to-day, when streets extend for many a weary mile beyond it. Luckily for the amenities of the site, in 1842 Victoria Park, which adjoins it, had been laid out and dedicated to the public use, and the presence of this open space must benefit the quality of the atmosphere of the hospital. Although in 1823 the name was changed to the lengthy but descriptive one of "the City of London Hospital for Diseases of the Heart and Lungs," it will be long before it ceases to be familiarly known as the Victoria Park Chest Hospital. This attractive booklet is rendered the more interesting by its

appendices. The first contains brief notices of some of the distinguished men who have served on the honorary staff. Among these the first and fullest is that of Dr Thomas Bayly Placock (1812-1882), who was one of the two first netting physicians and "the guiding spirit of the institution and almost its ruler." Take so many of the founders of the charity, he was a member of the Society of Friends, but humility does not seem to have been one of his outstanding characteristics. Indeed, he was an autocrat, and his word was for long law in all departments of the hospital. Guy Babington of Guy's, Risdon Bennett, Andrew Clark, Henry Gawn Sutton, and all names which are writ large on the roll of distinguished physicians. In the note on Sir James Risdon Bennett, who was President of the Royal College of Physicians, it is stated that he held consultations in Finsbury Square up to the time of his last illness. This is an error, for, like his contemporaries, he moved to Cavendish Square some years before his death in 1891. In another appendix, for which most of the facts of antiquarian interest were supplied by Mr A Forbes Sieveking, will be found a very good account of Bethnal Green and Victoria Park. Bonner's Fields include probably the site of a country house that belonged to the Bishopric of London, and was occupied, it is believed, by that notorious persecutor of Protestantism, Bishop Bonner. But the most famous association of the neighbourhood is with the legend and ballad of the blind beggar of Bethnal Green, commemorated by public house signs and by the plays on the same theme by John Dry and Henry Chettle in 1659, by Robert Dodsley (played at Drury Lane in 1741), and that by Sheridan Knowles in the last century. Thus in three successive centuries the story has been commemorated in dramatic representations, and the suggestion seems reasonable that it might be once more illustrated by a local pageant in the twentieth century. There is very much else of interest in this pamphlet, which has a coloured frontispiece and two maps. It has been brought out by friends of the hospital without any charge on the funds of the charity, and it has our best wishes for its success as an appeal for funds.

SIR RICKMAN GODLEE'S BEQUESTS

SIR RICKMAN GODLEE died on April 20th, aged 76, and an obituary notice was published in our issue of April 25th (p. 809). He left estate of the gross value of £94,148, with net personalty £83,728. He made a number of bequests, which will take effect after his wife's decease. After certain specific bequests he left the residue of his property as to one-half to University College, London, and one-half to University College Hospital, London, £10,000 will go to the Medical School, £1,000 to the Students' Home, and the balance for the hospital, unless it shall be taken over or maintained by the public, when the one-half left to it will revert to University College. He left £10,000 upon trust, the income to be applied for travelling scholarships for students of University College Hospital Medical School who have held a house-surgeoncy and one other resident appointment at University College Hospital, and are, in the opinion of the committee, likely to benefit from visiting medical schools and scientific institutions abroad in this country. If in the opinion of the committee there should be a more suitable form of post-graduate study the scholarships may be applied for that purpose. In the event of the hospital being taken over by the State or municipality, or other public authority, the trust would continue as a fund to benefit students in the way indicated and not be merged in some general educational trust. He bequeathed £5,000 to the Royal Medical Benevolent Fund, and a like sum, including the amount of his debentures in the society, to the Royal Society of Medicine, to be applied as far as possible for the purposes of the library of the society.

THE POWER OF IRRATIONAL BELIEF

BY

THE RIGHT REV E W BARNES, Sc D, F R S,
Bishop of Birmingham

ON Thursday, July 21st, in the Abbey Church, Bath, preaching at the official religious service of the Annual Meeting of the British Medical Association, the Bishop of Birmingham delivered the following sermon, taking as his text—

"Wisdom is justified of all her children"—St Luke vii, 35

I cannot address members of the British Medical Association now assembled for their ninety-third Annual Meeting without expressing pleasure at the opportunity afforded me. I naturally share the regard in which the medical profession is held by all sensible men. My own status and interests—yes, and needs—have from time to time brought me into close contact with leaders of medical science in this country. I have had opportunities of measuring the value of their work and of realizing the generosity of temper and fineness of character which it can develop. I know of no other profession which more naturally leads to breadth of human sympathy. Your work will not allow you to form any false estimate of human nature or to ignore any of the fundamental instincts and appetites of man, but intimate knowledge makes a good physician compassionate and not cynical, and many of you have thus been led to revere the human body and the spirit of which it is the shrine as the noblest work of God on earth. The physician who, through the practice of his art, acquires this truly religious reverence learns to worship God through service to his fellow men. Members of your profession are to no small extent guardians of public morality. Your professional work constantly reminds you of the close connexion between clean living and good health. You probably receive more confessions of grave importance than all the clergy of the various branches of the Christian Church altogether. You are bound by principles of professional honour not to disclose what is thus revealed, and although such an obligation would be legally recognized you know that in fact no High Court judge would allow you to be forced to violate the confidences which you receive. Because you are thus consulted and thus trusted you have immense opportunities of influencing the personal lives of your patients. A wise and sympathetic physician of high ideals can hardly fail to be a moral inspiration to the section of the community which he serves. His influence will make for social righteousness; he will feel impelled to seek to preserve the purity of family life. If his work be among the poor he will naturally be sensitive to their special hardships, and in particular at the present time to the evils of overcrowding, but wherever his work may be he will be able to advise those concerned with social welfare, because he will have a knowledge more direct and more extensive than others can gain.

Superstition the Bane of Medicine

There are some among us who assume that medical science should, by religious teachers, be mainly considered in relation to public morality, but I will to-day emphasize the religious importance of the regard which physicians and surgeons must necessarily pay to accurate knowledge, and therein I would say that superstition, excess of belief—belief which does not rest on a basis of accurate scientific investigation—is the bane of medicine no less than of religion. Every thoughtful physician, like every thoughtful clergyman, recognizes the power of irrational beliefs. Neither is ignorant of the uses—sometimes the base uses—which can be made of such a power. Neither, if he is wise, will allow the immediate utility of irrational emotion to blind him to its dangers. Especially is this true at the present time. We are living in a strange world, where lax morality is matched by lax thought. If some present tendencies are permanent Western civilization will not escape the intellectual degeneration which finally ruined Graeco-Roman civilization some fifteen centuries ago. To take the case of medical science, until quite modern times, the highest level reached by that science was attained by the Hippocratic school in the great age of Greece. During the last century accurate clinical observations and patient research have caused medical science first to reach, and then far to surpass, that level of the

great age of Greece. The progress which has been made in medical knowledge and surgical skill since (say) the time of Charles II is amazing. Yet are we sure that we can preserve what has been won? Is its value safely rooted in popular esteem? The great triumphs of Greek medicine were gradually, but not the less definitely, ignored. Medicine ceased to be scientific as it became slowly barbarized by the folk beliefs which, especially after the Christian era began, acquired new vitality. In fact, from science the populace of the ancient world turned to quackery, old wives' lore, magical charms, visits to healing shrines—all the paraphernalia of primitive health cults—renewed their ascendancy, and the same recrudescence of magic and superstition which infected medicine found expression in religious extravagance.

Intellectual Barbarism

Are there any signs to-day that people turn from scientific medicine to quackery? You have, I am glad to say, an organized authority which your profession never attained in the ancient world but can you, with all that authority and with the abundant knowledge which it guards, prevent recourse to faith healers and osteopaths and charlatan psychoanalysts? You might retort and ask whether bishops can prevent the recrudescence of thinly disguised magic in Christian worship. The sad truth is that we are all subject to the same pressure of irrational belief. As that great physician, Sir Clifford Allbutt, said to me in one of the last conversations which I had with him, 'When superstition attacks religion it also attacks medicine. Religion is the first to feel the effects of an uprush of intellectual barbarism. This is natural, for there is in the very best spiritual understanding an emotional element associated with those very judgements on which all true religion is based. The history alike of philosophy and theology shows how difficult it is for humanity to apply reason successively to the spiritual valuation of human life, and my growing expression of reason will therefore show itself rapidly in religious extravagance. But the same impatience of rational thought will gradually spread to other regions, because there are no absolutely water-tight compartments in the human mind. The temper of superstition involves dislike of scientific methods, of accurate reasoning. After manifesting itself in religion, it will turn upon scientific medicine because that is the branch of science most closely concerned with ordinary life. The obscurity which, as we all know, surrounds the influence of the mind upon the body gives many opportunities to irrational theories, and if the doctor fails, thinly veiled magic may succeed and when once the idea gains sway that the universe is non-rational for human thought, when once men set aside God's gift of reason, then scientific progress is doomed.'

The Bishop went on to speak of the reaction from scientific theology in his own Church. If the present tendency to go behind the Renaissance (when the scientific spirit was reborn in Western Europe) to medieval folk beliefs prevailed in the Church, the prospect before rational medicine and, indeed, before all forms of intellectual progress was gloomy. The whole world to-day was laughing at the State of Tennessee, where religious fanaticism was arrayed against a well attested scientific theory. But opposition to evolution was not less sensible than many beliefs associated with the various cults which during the last half century had shown disquieting vitality.

The Scientific Temper a Recent Acquisition

Dr Barnes proceeded

You yourselves must often ask why superstition makes a stronger appeal to-day, as I believe in fact it does, than half a century ago—why apparently well educated men and women among your patients will leave you for self-assertive charlatans. There are some obvious reasons. The scientific temper which trusts in reason is a recent acquisition of humanity. In comparison with the immense antiquity of the human race it was born but yesterday. Like all recent acquisitions, its place in our mental make-up is insecure. Then, too, it is exacting and men are mentally lazy. And, moreover, during the last century science has made such extraordinarily rapid progress that the mass of men are bewildered by the change of outlook to which it has led. They feel that their spiritual intuitions no longer rest on a firm basis. The feeling of course, is false, but it is there. They distrust intellectual novelty, and in the recoil turn to primitive fancies. There is also at the moment the disturbing effect of the war, which led to psychological distress

without a parallel in recent history. The war created a situation in which mass suggestion of the crudest kind was unusually potent.

In the modern educated world superstition is really of the nature of mental disease. Irrational beliefs spread by that power of suggestion which, if sufficiently strong, penetrates the barriers by which reason should prevent its entrance to the mind. Men and women such as popular novelists who succeed by appealing to popular fancy are naturally sensitive to emotional currents in the community. Such yield more rapidly than others to unreasonable beliefs which gain popular approval, and spread them by their writings. For the same reason religious leaders and enthusiasts who are similarly sensitive have their critical faculty inhibited. Without any intellectual dishonesty they yield to suggestion, and will make what is really an obsession the basis of an elaborate argument.

No 'Short Term' Optimism

Unfortunately, it is more easy to explain the spread of false emotionally coloured ideas than to suggest the remedy. As the Greek Roman civilization showed intellectual degeneration may conquer a whole group of peoples, but this probably happens only when the best stocks die out. Civilized progress is maintained, not by the many, but by the chosen few, and we must trust that Western civilization will continue to throw up an adequate number of men and women of intellectual strength sufficient to resist irrational emotion. After all man is a reasoning animal, and therefore in the long run reason will prevail. As the Christian would say, God is both wisdom and love. He has made man to think. His thoughts no less than to obey His laws. In the thought and conduct of men progress and reaction alternate. Human history and pre-history taken together justify the Christian optimism that in the long run progress is sure. But it is certainly not uniform, nor even approximately steady. We cannot be short-term optimists. At present, I fear, there is little reason to hope that English men and women of the twentieth century will show the solid good sense of the Victorian era now commonly despised.

Nevertheless we must continue to proclaim our faith in reason for it is only through the operation of the divine gift of rational consciousness that we can advance in knowledge of God's world and of God's ways. I personally believe that through such faith in reason we shall be led to accept more wholeheartedly and more intelligently than heretofore the revelation of Christ. Your great profession is founded upon loyalty to truth. A determination to discover truth is the very basis of the scientific method through which medical and surgical knowledge advances. When we recall that all the faculties of man—bodily, mental, and spiritual—form a definitely planned unity, we can affirm that the progress of medical science must serve the cause of true religion. It will be associated with an enrichment and with a purification of spiritual understanding and I believe that amid all change such understanding will continue to be centred on Christ, who said, 'Wisdom is justified of all her children.'

INTERNATIONAL CONGRESS OF HISTORY OF MEDICINE AT GENEVA

THE fifth International Congress of the History of Medicine opened in the Athens at Geneva on Monday, July 20th, and continued during the ensuing week. The President of the Congress was Dr Charles G. Cumston, Professor of History of Medicine in the University of Geneva, and a number of representatives from various public bodies were present at the opening to welcome members of the Congress.

Inaugural Ceremonies

In his inaugural address the President referred to several distinguished physicians of Geneva who had in the past interested themselves in medical history. Daniel Leclerc, in 1696, brought out his great work on the history of medicine, some twenty-nine years before Freund published his *History of Physic* in London. Leclerc, in addition to being a historian, was a very successful practitioner, and people came from far to consult him. An earlier Geneva physician was Jean Antoine Sarrasin, who in 1598 published at Frankfurt an edition of Dioscorides in Greek and Latin. He wrote also a treatise on the plague, published at

Geneva in 1571, in which he spoke of cancers of this disease, a subject to which Calvin had also referred. During the seventeenth century Bonetus published at Geneva, in 1679, his celebrated *Scapulicrurum*, one of the earliest studies of pathological anatomy. Many other physicians of Geneva had enjoyed fame beyond the city, and among those of more recent times he mentioned Lionelin, Maunon, and Rilliet.

Dr ANDRÉ PATRI, President of the Medical Society of Geneva, next extended a welcome to the Congress on behalf of the doctors of the city. He reminded his hearers that Geneva and Switzerland generally had been famous for centuries on account of the attention paid by various medical men to ophthalmology and to the improvement of operations for cataract.

M ADOLPHE OTTAVIANI, expressing a welcome on behalf of the Council of State, said that Geneva took a great interest in the history of medicine because this was an important part of the history of the world. There was in medicine some part of intuition or divination which had given rise to the expression "the art of healing"—that was, an ability to recognize the means of warding off death. The Roman physicians of the declining empire had struggled, along with the moralists, for a return to simplicity of manners, like those of our day.

M GEORGES WEHNER (Rector of the University of Geneva) recalled as a point in local history the foundation of the Red Cross and the aid of the wounded. It was, he said, of as much interest to the doctor to study the history of medicine as it was to the jurist to study the history of law.

Professor TRICOT-ROUX of Antwerp, President of the International Society for the History of Medicine, declared that while the history of politics was considered an indispensable study, the history of science had long been neglected. Nevertheless, a fertile theory was the result of the effort of an infinity of obscure workers. Research into this subject helped to prevent pride, for every doctrine passed through stages of youth, maturity, and senescence, and the study of this chain constituted the history of medicine.

Professor EUGÈNE PITTARD of the University of Geneva then delivered an interesting lecture on the prehistory of medicine, illustrated by skulls and implements, chiefly from French and Swiss burial mounds. Among prehistoric peoples, he said, trephining of the skull was a fairly frequent occurrence. It was usually carried out in the parietal, less frequently in the occipital, region, sometimes it had taken the form of long grooves running from the frontal to the occipital region, but not penetrating the skull completely. These operations had apparently been effected by flint instruments, which he demonstrated, it must, he thought, have taken at least an hour of seeping to make a large opening in an adult skull. Whether the operation was carried out to relieve symptoms or for some social or therapeutic purpose it was impossible to say, as regarded recovery from the operation, it had evidently been quite successful.

On the evening of the opening day a reception was held by the President and Mrs Cumston in the Beigues Hotel. The members of the Congress were entertained at a concert by Mlle Cougnaud, Marguerite Roesgen, and Lily Ganzoni of the Geneva Conservatoire. A special feature was the performance of an ode in honour of the medical profession, which had been composed and set to music by one of these artistes for the occasion of the Congress.

Fairly Eighteenth Century Theses

On Tuesday, July 21st, Sir D'Arcy Power, President and Honorary of the Congress, read a paper on the *Disputationes chirurgicae selectae*, which were edited in six quarto volumes by Albrecht von Haller at Bern in 1755 and 1756. The theses were written for the doctorate of medicine in the various European universities between 1699 and 1742, and were interesting partly because they showed how early some modern surgical discoveries had been recognized, partly on account of the light they shed on the social habits and customs of the times, and partly because they gave contemporary methods of surgical treatment and proved how free was the interchange of ideas

between the surgical centres in Europe. Sir D'Arcy Power mentioned an interesting thesis on sinusitis, in which the various forms of inflammation were detailed, and the treatment of an empyema in the rutium of Highmore was given. Another thesis dealt with the radical cure of hernia, and another asked whether there was not a better treatment for aneurysm than by the methods of Antyllus and Ael. The passage of a tubo was recommended for the relief of patients suffering from cruecious stricture of the oesophagus as early as 1740, whilst some of the candidates showed that they had performed experimental surgery upon which to found their theses. Details were given of a case of acute perforation of a gastric ulcer after which the patient survived twenty-seven years, and of another case in which two and a half feet of gangrenous ileum was removed, the man living for twenty-two years, passing his motions per anum, and the post-mortem examination showing that the intestine had become "short-circuited." One of the theses dealt with wounds of the knee-joint and gave details of injuries sustained in Marlborough's campaigns of 1705-7. It showed that Claudius Amyand—afterwards sergeant-surgeon to King George II—had acted as a military surgeon in Flanders, a fact hitherto unknown. There was also an account of a man whose reducible hernia became strangulated during "a solemn boar hunt," which lasted several days in the depth of winter near Stuttgart, and another of the town surgeon who developed a strangulated femoral hernia as a result of drinking a large draught of ice-cold beer one morning in the dog days when he had overfatigued himself with a long round of visits. Perhaps the gem of the collection, Sir D'Arcy Power concluded, was the thesis dealing with the blindness of Tobit, which was reminiscent of a chapter from Sir Thomas Browne's *Vulgar Errors*.

Voltaire and English Doctors

Dr J. D. ROLLESTON (London) stated that though there was no record of Voltaire having been attended by any practitioner for the various illnesses from which he suffered during his residence in London (1726-29), he appeared to have been acquainted with several leading medical men of the time, especially Sir Hans Sloane, Cheselden, Mead, and Friend (whose death he described in an English letter), as well as with other medical Fellows of the Royal Society (especially Arbuthnot and Pemberton). He was himself elected some years later (1743) to be a Fellow of the Royal Society. Among the less known doctors whose acquaintance Voltaire made in London was a certain Dr Towne, the author of a work on the diseases most prevalent in the West Indies, who translated into English part of *La Henriade*. Dr Rolleston pointed out that Voltaire had some knowledge of the classic English medical writers, as shown by allusions to Harvey's works on the circulation and on generation, and also to Sydenham. During his old age Voltaire received visits from several English doctors, of whom the best known were Oliver Goldsmith, Samuel Sharp, surgeon to Guy's Hospital, and John Moore, who had left a striking portrait of the aged philosopher. Dr Rolleston showed a complete list of 343 English subscribers to *La Henriade*, including the names of four doctors—Mead, Misaurin, Broxholme, and Chamberlain—and he also exhibited a hitherto unpublished portrait of Voltaire by Woolledge, in possession of Mr A. Forbes Sieveking.

Robert Whytt of Edinburgh

Dr JOHN D. COSMIE (Edinburgh) contributed a paper upon Robert Whytt, an eighteenth century neurologist. Whytt had been made professor of medicine in Edinburgh at the early age of 33, but had all his life been overshadowed by his more vigorous contemporary Cullen. Whytt died at the age of 52, and Cullen succeeded to the chair at the age of 63, but still maintained a great reputation and a huge consulting practice, so that Whytt was largely forgotten. Posterity had hardly done justice to the original work that Whytt had produced. His early work had dealt with a subject which at that time was considered very important—namely, the search for remedies to dissolve urinary calculi. Whytt's research had had the effect of stimulating his friend Joseph Black to investigate the

properties of magnesium alba and other ill-dine substances, and thus led indirectly to the discovery of the first known gas, "fixed air" or carbon dioxide. Whitt, in his treatise on the *Involuntary Motions of Animals*, was probably the first to localize the mechanism for a reflex act, showing that the brain was unnecessary and that the reflexes for upper and lower limbs were complete in the upper and lower parts of the cord respectively. Whitt's essay on *Sensibility and Irritability* brought him into conflict with Haller, then the great hierarchy of physiology. The dispute as to the nature of muscular action was rather a dialectic one, but Whitt in the opinion of his contemporaries got the better of Haller. Whitt's *Observations on Various Disorders*, an elaborate treatise published in 1764, contained an important doctrine regarding the "sympathy" of the nerves and Whitt in some respects anticipated the modern idea of "reflexed pain." Whitt, in a small paper published after his death, gave the first clear presentation of tuberculous meningitis. An interesting point in regard to one of his cases of this disease was that the patient was seen in consultation in 1764 with Professor Monro (*secundus*). After death a large opening was found between the lateral and third ventricles, and being discovered by Monro also in normal brains came to be known as the foramen of Monro.

The Elsevier Press

On Wednesday, July 22nd, Dr E. B. KENNEDY (Philadelphia) read a paper upon medical literature of the seventeenth century as exemplified in the Elsevier Press. A very important indication of the medical boom in demand during the seventeenth century was gained by considering the books published and sold by the famous house of Elsevier in the Netherlands during this century. When one examined the catalogue issued by Daniel Elsevier at Amsterdam in 1674, one found in it 1,641 titles of medical books by more than two hundred authors. Almost all the more celebrated writers of antiquity and of the sixteenth and seventeenth centuries figured in the list, but most of the works were written by some eight or ten authors of the epoch whose names were to day quite forgotten. Thus Læcius is represented by over 50 titles, Deusingius by 34, Sennet by 22, Sebæus by 21, Major by 14, Aldrovandi by 13, Rolingius by 12, Severini by 11, Primerosius by 11, while Harvey, Willis, Celsus, Hippocrates, Sidenham, and other notable writers were only represented by one or two books each. It was evident, however, from various facts that in this the Elseviers were complying with the popular demand of the time.

Hygiene in Early Civilizations

Mr C. J. S. THOMSON (London) contributed a paper dealing with hygiene and public health in the early civilizations. He referred to the preparation of soap among the early Sumerians (2,500 B.C.), the teachings of the early Greek philosophers and physicians upon general sanitation, and described in detail the arrangements of water supply and baths in ancient Rome. Other papers contributed were by Dr WICKLESHAMER (Strasbourg) on syphilis at Geneva in the end of the fifteenth century, by Dr J. W. JONSSON (Copenhagen) on a letter of Paracelsus on poisons, by Dr J. W. COURTNEY (Boston) on Benjamin Waterhouse, American pioneer, Professor JEANLEUR (Paris) on magic in medical treatment throughout the ages, etc.

Paracelsus and Medicine

Dr R. O. MOON (London) contributed a paper on Paracelsus and medicine. This stringest of figures in medical history, he said, was reviled by his enemies as a vulgar and ignorant charlatan, while hailed by his disciples as the inaugurator of a new epoch in medicine and as a man of deep religious belief and purity of life. Though called no more than the "father of medicine," he had no real enthusiasm for the defenders of religious freedom. Like all prophets of revolution he had a sovereign contempt for learning, and boasted that he had read no book for ten years. "The sick," he said, "should be the doctor's school." As a teacher his success was due to his lectures being given in German instead of in medieval Latin, his success as a practitioner owed to his careful observation

of the individual patient, to his knowledge of chemistry, and to the free use of opium. But, above all, much of his influence came from the neo-Platonic philosophy, which had been awakened by the Renaissance and suffused most of his works. Paracelsus was undoubtedly a mystic, but, like Pythagoras, his mysticism was not incompatible with practical medicine. Neo-Platonism, unless handled by an intelligence more disciplined than that of Paracelsus, readily passed over into anti-intellectualism, and from this reproach the writings of Paracelsus were not free.

Early History of Dentistry

In a paper on the history of dentistry in England up to the beginning of the nineteenth century Mrs LARRY JAMES, L.D.S.D., advanced the thesis that the current belief that the modern dental surgeon was an offshoot from the stock from which the general surgeon had sprung—namely, the guilds of barbers and barber-surgeons—was erroneous, and submitted evidence, derived from a careful reading of all available original documents, to prove that a special type of dental practitioner, universally known as the tooth-drawer, could be traced continuously in literature from the fourteenth to the nineteenth centuries. In 1376 "tooth-drawing" was included in the first memorandum of the Company of Barber-Surgeons, and in England's *Visions of Piers Plowman* (1377) a tooth-drawer was mentioned. Evidence was advanced that in the fifteenth and sixteenth centuries the increase in dental disease brought the tooth-drawer more into prominence, until in the seventeenth century he became the "Operator for the Teeth"—one of the titles adopted by Charles Allen in his book published in 1686. The title "dentist," introduced from France about the middle of the eighteenth century, was not generally adopted until a century later. The scientific teaching of dentistry, originating in the works of John Hunter, followed by the lectures of James Roe in 1782, finally brought dentistry into recognition as a learned profession.

On the evening of Wednesday, July 22nd, the members of the Congress were received by the Administrative Council of the City of Geneva in the Palais Lyriad. On Thursday, July 23rd, a whole day excursion was made by steamer to the head of the Lake of Geneva, the party being entertained to lunch in the Castle of Chillon by the physicians of Montreux, and to dinner at L'Arrière-Bains by the administration of this spa.

The Congress resumed its sittings on Friday, July 24th, and ended with a banquet in the Hotel des Bergues.

Canada.

[FROM OUR OWN CORRESPONDENT]

CANADIAN TUBERCULOSIS ASSOCIATION

THE twenty-fifth annual meeting of the Canadian Tuberculosis Association was held on May 14th to 16th in Montreal. Great regret was expressed that, owing to illness the President, Dr C. D. Piffitt, of the Calidar Sanatorium, Gravenhurst, Ontario, was unable to be present. Dr A. Roussier, Dean of Laval Medical School, Quebec, was elected the new president. Most of the meetings were held in the Mount Royal Hotel, but Dr F. W. Archibald, Professor of Surgery at McGill University, gave a clinic at the Royal Victoria Hospital on surgery in tuberculosis. Visits were paid to the Institut Bichat and to the Royal Edward Institute. A meeting was also held under the auspices of La Société médicale de Montréal, indeed, a particularly pleasing feature was the number of French speaking physicians and nurses who were present. Several papers were given in French, one, especially good, on the progress of antituberculosis work in France, being by Dr Willard B. Soper of Saranac Lake, N.Y.

An Urban Health Demonstration

On the last day of the conference a large number of members visited Three Rivers on the St. Lawrence River, half-way between Quebec and Montreal. Here, in a town with about 27,000 inhabitants, and in the little town of Cap

de la Madeleine, with a population of some 7,500, just across the St. Maurice River, a "health demonstration" was begun in December, 1923, and will continue until December, 1928, of the same type as that which was undertaken at Framingham, Massachusetts. The work is being done by the Department of Health of the Province of Quebec, with the financial assistance of the Canadian Tuberculosis Association, the Federal Government, the Canadian Red Cross Society, and the Sun Life Assurance Company of Canada. The survey of tuberculosis was begun in May, 1923, and a dispensary was opened. An active educational campaign has been carried on and the public have become conversant with the dangers of the disease. Before the centre was established a survey showed that only 70 patients with tuberculosis were known to the physicians of the town, they had not been reported and did not receive home visits. During the first year's work 118 cases were recognized, and 57 others were found in the second year. At present 195 patients with tuberculosis are being cured for, and 889 others are under observation, they suffer from adenopathy, ure contracts, or the diagnosis is doubtful. Altogether 3,234 persons have been examined. Of these, 583 were factory workers, and the diagnosis of tuberculosis in some degree was made in 231. This seems an extraordinarily high rate of morbidity, but it must be noted that those who sought examination were those who were most impressed with their need of it. In a college with 400 pupils from 11 to 20 years of age, 330 were examined. 31 cases of tuberculosis were found, 45 others are still under observation, and in 254 the diagnosis was negative. Besides this tuberculosis work maternal welfare and child welfare clinics have been established. The death rate from gastro-enteritis amongst infants up to 1 year of age has been greatly reduced, for in 1915-22 the average was 89.5, from May 1st, 1923, till May 1st, 1924, it was 49, and in the following year it fell to 41.4. Such work as this cannot but be far-reaching in educating the French Canadians and English speaking Canadians in the principles and beneficial results of hygiene.

Travelling Diagnostic Clinic

Dr. G. C. Bink's paper on a travelling chest diagnostic clinic told the story of a new effort in the campaign being waged against tuberculosis. It is a clinic established by the Provincial Board of Health of Ontario. On receipt of a request of the local practitioners and the local medical society a physician, well trained in the diagnosis of the disease, accompanied by a nurse, spends a week examining all patients referred to the travelling clinic. A portable clinic machine is part of the equipment. Altogether twenty-two centres were visited, 721 patients were examined, and out of this number 133 were diagnosed as "suspect," 81 as having active tuberculosis, and 63 as presenting evidence of "arrested" disease.

OSLER JOHNSTON McCRAE

Three memorial tablets were unveiled on May 27th by Dean Cahsle (of Christ Church Cathedral) at the Montreal General Hospital, to the memory of three men who had worked there—Sir William Osler, Bt. (1849-1919), Walter Galt Johnston (1863-1902), and John McCrae (1872-1918). The most important part of their work there was in the pathological department. Osler, as his great friend Dr. F. J. Shepherd, emeritus dean of the McGill Medical Faculty and emeritus professor of anatomy, said, was appointed pathologist to the hospital in 1876, and was physician from 1878 until 1884, when he became professor of medicine in Philadelphia. At the hospital he made his excellent post-mortem observations which formed the basis of the pathology of disease so well and so fully taught in his *Principles and Practice of Medicine*. Dr. R. F. Rutten, Professor of Chemistry at McGill University speaks of Johnston's work in pathology and bacteriology at the hospital and in public health and medico-legal pathology in the University. His sudden death after infection received at an autopsy robbed Canada of a brilliant scientist. Dr. C. F. Martin dean of the McGill Medical Faculty, then referred to McCrae, who was Fellow in pathology and pathologist to the hospital. Later he became assistant physician at the

Royal Victoria Hospital and lecturer in medicine at McGill. He was a splendid teacher for undergraduates, and had the happy knack of giving only the salient features, the really important points, in his clinics. He served during the South African war as a combatant, and in the European war with the allies, and later also in France with the Canadian Army Medical Corps. Before he died he was appointed medical consultant to the Fourth Army. He is now widely known as the writer of the verses "In Flanders Fields," and each year his memory is reawakened in us when poppies are everywhere sold on Armistice Day.

ANTI-VACCINISTS AND SMALL-POX

In the Province of British Columbia the activities of the antivaccinists have been very annoying. During the last year or so there has been a good deal of small-pox in Vancouver and its vicinity, slight cases have passed unnoticed, but 300 have been reported in Vancouver since the beginning of the year. The United States insisted that all persons travelling south across the line should show evidence of recent vaccination. The Provincial Health Department instituted general vaccination. The antivaccinists tried to persuade the citizens that a small-pox alarm was being spread by the physicians in order to line their pockets with vaccination fees. The antivaccinists have even tried to work up a scare about "bovine syphilis" with its dangers for human beings. The campaign of vilification and exaggeration was, it is said, carried too far, so that the ordinary sensible citizens became weary of it.

INSURANCE COMPANY'S GIFT FOR POST GRADUATE LECTURES

At the annual meeting of the Canadian Medical Association at Regina it was announced that the Sun Life Assurance Company had given thirty thousand dollars to the association to establish a scheme for post-graduate lectures and teaching throughout Canada. The work will be carried out as it has been during the last few years in Ontario under the Provincial Association (see *BRITISH MEDICAL JOURNAL*, 1925, i, 44) by sending out medical men at the request of medical societies of towns or of county districts, who attend the regular meetings and lecture upon any one of a wide range of subjects offered by the central committee. This very generous gift is greatly appreciated by the medical profession.

Scotland.

EPIDEMIC OF MILK POISONING AT ABERDEEN

An outbreak of food poisoning which at first affected between thirty and forty people in the city of Aberdeen commenced on July 7th. On July 8th there was something in the nature of an epidemic, and eight patients had to be removed to the Aberdeen City Hospital. The symptoms were vomiting, which made its appearance about eight hours after milk had been consumed, accompanied by a sudden onset of diarrhoea and vomiting which was extremely acute and painful. By July 9th over 300 persons had become affected by the epidemic, which was mostly confined to the Rosemount and central area of the city. The outbreak was traced to three dairies in the city, and the supply of milk from them was stopped, by the end of the week the public health authorities had the epidemic completely in hand. The bacteriological examination of the milk showed one of the organisms of the typhoid dysentery group which apparently had been derived from a bare or farm worker. None of the patients died.

HEALTH OF EAST LOTHIAN

Dr. George L. Richardson, medical officer of health for East Lothian in his annual report for 1924, refers to the East Fortune Sanatorium, which has recently been opened. In the county of East Lothian during the year 54 cases of tuberculosis of the lungs were notified, of whom 24 died, and 44 cases of non-pulmonary tuberculosis of

whom 11 died. The treatment of tuberculosis in 1st Lothian will in the future be on a plane higher than in the past. The report refers also to an outbreak of acute infective jaundice, which occurred in the western area of the county and involved 14 persons, of whom twelve were coal miners. Among these 4 deaths occurred. A bacteriological examination had been made of rats from underground workings and from the surface of pits and also of rats from rats fur removed from pits. Of nineteen rats examined ten were found to be infected. Infection was also found in field mice. The organism has been found in slime taken from the roof of a wet section of a pit which appeared to be inaccessible to rats and this proved that there were other sources besides the rat whereby man might become infected.

EDINBURGH SANITARY DEPARTMENT

In presenting the annual report of the sanitary department of the City of Edinburgh Mr. Allen W. Ritchie, chief sanitary inspector, drew attention, among other things, to the pollution of the air and to overcrowding in houses. Though Edinburgh was not so seriously affected by smoke pollution as the more industrial cities, yet the position could not be regarded as satisfactory. The law required remodelling to enforce the adoption of newer methods of heating in dwelling-houses and for motive power for factories and transport. Overcrowding in the smaller houses became more serious year by year. The number of overcrowded houses which came to the knowledge of the department during the past year (1924) exceeded that of the previous year by 210. In a considerable number of cases the condition had prevailed for several years, and in some one-apartment houses as many as seven, eight, and ten persons were found living in a single room, while in several two-roomed houses ten, eleven, twelve, fourteen and in one case sixteen persons were found. As the majority of these overcrowded houses were in the congested areas of the city the matter was all the more grave. The new schemes under the corporation and private enterprise had had their effect in easing the housing difficulties of many occupants of the better class of houses.

England and Wales.

LEPSOM COLLEGE

FOUNDER'S DAY at Ipswich College was celebrated on Saturday, July 25th, when a service was held at midday in the chapel, and the prizes were distributed in the afternoon by Earl Beauchamp. The headmaster, in the course of his annual statement referred to the substantial progress that had been made during the year in the school, out of forty-two candidates forty-one had secured school certificates, and thirty-two had been exempted from matriculation. Outstanding features were the winning of an open history scholarship at Hertford College, Oxford, an open science scholarship at Clare College, Cambridge, and a double first in a Cambridge Tripos. The numbers in the school had passed all previous records, and until further accommodation was provided no more boys could be admitted (we referred on July 4th (p. 19) to the extensions that were under consideration to meet this and other needs). Dr. E. N. Gardner was leaving the school after thirty-five years' service; he had been awarded the honorary degree of D. Litt. at Oxford. In the evening there was a successful choral performance of *The Midado* by the College musical society.

SCARLET FEVER OUTBREAK IN PORTSMOUTH

Portsmouth Health and Housing Committee has received a detailed report by Dr. A. Means Fraser, medical officer of health for the borough, of a limited outbreak of scarlet fever which occurred at the end of May and the beginning of June. On May 29th, 21 cases were notified, followed by 21 on May 30th,

14 on May 31st, 8 on June 1st, 6 on June 2nd and 1 on June 3rd the total number, including a few cases in which notification was delayed, amounted to 83. The majority of the patients were found to have partaken of ice cream which had been bought at branch shops in different parts of the town, belonging to one particular dairy firm. The man who prepared this ice cream had been assisted by a boy who, on May 30th had been diagnosed as suffering from scarlet fever. During the previous week he had had a sore throat, but the rash did not appear until the night of May 25th. His duty had been the putting of the ice cream into tins for distribution. No further cases occurred among persons who consumed this ice cream after May 29th the last day on which the boy was at work. Three cases of scarlet fever occurred amongst other persons employed by the dairy firm, but it did not appear that any of these could be held responsible for the spread of infection. A total of 63 of the 83 patients had eaten this ice cream within a few days of being taken ill, the disease starting within a few hours to four days. Dr. Means Fraser pointed out that, so far as he was aware, no cream had not been previously incriminated in an outbreak of scarlet fever and that the incubation period in several of these cases was far shorter than would have been expected. No other factor could be discovered which was common to a large proportion of the cases, and he felt that a coincidence could hardly be assumed since so many people had contracted the disease after eating a plentiful supply of ice cream which had had ample opportunity of having become infected. There was no evidence that scarlet fever had been contracted from the milk supplied by the firm, and as soon as the sale of the ice cream stopped the outbreak ceased. Every assistance in investigation was rendered by the dairy firm, who were quite unaware that the boy was not in perfect health at the time he was working for them. The outbreak was mild in type.

Correspondence.

THE TREATMENT OF PLACENTA PRÆVIA

SIR—I am afraid this letter will lose its interest owing to the delay that must occur before its publication is possible. I regret very much that I find myself in direct opposition to Professor Watson for whose opinions and work I have the greatest respect and admiration, but in the present instance he is in direct conflict with facts as I know them. Moreover, should his opinions gain the ascendancy, they will undo a portion of what I have tried to do in New Zealand with the object of reducing maternal mortality.

I have just read the report of the discussion on the treatment of placenta prævia which took place at the Edinburgh Obstetrical Society on January 14th last (*BRITISH MEDICAL JOURNAL*, February 21st, p. 363). From this I understand Professor Watson's view to be that Cæsarean section is the treatment of choice for severe cases. As an alternative there is the vaginal "prek plus version" bys, bipolar and internal version" while for the mild cases there is rupture of the membranes with or without the application of forceps.

In 1897 I published the first edition of my *Short Practice of Midwifery*, in which I reproduced the teaching of Sir William Smith, whose Mastership at the Rotunda Hospital had ended a year before. In this edition the treatment of placenta prævia is given as follows:

If the patient is not in labour 'the best treatment then is that recommended by BRYANT HICKS. It consists in turning the foetus by bipolar version into a breech presentation rupturing the membranes drawing down a foot and leaving the rest of the delivery to nature. If it be a case of central placenta prævia the fingers must be pushed directly upwards through the placenta in their attempt to seize the foot. This treatment at both cheeks the haemorrhage by the pressure of the breech or the back of the child against the placenta and brings on labour. A piece of gauze should be tied to the foot and if further haemorrhage occur light traction on the gauze will check it by drawing down

more of the breech. This treatment requires two conditions to be present: (1) The membranes must be unruptured, (2) the os must be large enough to admit at least two fingers.

The first condition is practically always present unless indeed an ignorant attendant has ruptured the membrane. The second condition is present in more than 99 per cent of all cases of placenta previa in which the patient is bleeding. In the rare instances in which it is not present, plug the vagina and leave the plug in for a few hours. The os will then be found to be sufficiently dilated to allow version to be performed.

If the patient be getting strong labour pains when the hæmorrhage commences, rupture of the membranes is often sufficient to check the bleeding. If the hæmorrhage still continues the child may be delivered by the forceps, if the head be fixed and the os dilated. If these conditions be not present the child may be turned by internal version and the rest of the delivery left to nature.

In the ninth edition of the same book, published in 1924, the treatment of placenta previa is described in identical words, except that I have given up the use of the sub-junctiva suture. In addition, it is stated that Cæsarean section is permissible when the placenta is central, the infant viable, and the mother has not been unduly weakened by previous hæmorrhages. Now this persistence of an identical teaching from 1897 to 1925 is the result either of an obstinate conservatism that will not change or of a decisive and favourable experience gained during this period. Which it is I will ask Professor Watson to say when he has considered the following figures.

In 1896 Sir William Smiley's Mastership at the Rotunda Hospital ended. During it he had treated in the hospital 55 cases of placenta previa, with one death. The late Dr Purser ended his Mastership in 1903, and in that date 108 cases had been treated, with three deaths. Dr Hastings Tweedy ended his Mastership in 1910, and by that date 149 cases had been treated, with four deaths. My own results were not so good, and, by the end of 1919, 230 cases had been treated, with fourteen deaths. When the last edition of my smaller book on midwifery was published in 1924, the statistics of three years of Dr FitzGibbon's Mastership were included, bringing the total figures since 1889 to 264 cases, with fourteen deaths, a percentage mortality of 5.3. As Professor Watson says, many cases are admitted to hospital when moribund, and in the statistics I have quoted such patients account for a number of the deaths. I do not think any operator would try to do Cæsarean section on such patients, and so it would not have saved any of them. Consequently, when we compare the results I have given with those of Cæsarean section, such cases should be omitted. If this be done we shall find that the treatment I have described gives a mortality rate of about 3 per cent in non-moribund patients, while Cæsarean section gives a mortality of 7.1 (Watson) or 11.5 (Holland) in patients whom we must assume were also non-moribund.

The treatment I have described has been carried out consistently at the Rotunda Hospital, with a single exception, since 1889, unless Dr FitzGibbon has altered it in the last few years, and it is a very different treatment from that which has given in Edinburgh a mortality rate of 13 per cent. It does not consist in the use of the "pach-plus version, brigs, bipolus and internal version." It consists, in serious cases, in which the patient is not in labour, simply in the adoption of version (whatever form is best, and usually a combination of external and bipolus), bringing down a leg, and leaving the further delivery to the natural efforts. It condemns the use of the pack as a grave danger, because of the necrosis of the uterine sinuses to the uterine orifice and the consequent risk of infection. It condemns efforts at dilatation, other than that implied by the passage of two fingers through a soft and partially dilated cervical canal, because of the ease with which the cervical tissues tear in these cases and of the proximity of large blood vessels to the cervix. It condemns any attempts to hasten delivery, unless the patient is in the second stage and the uterus is contracting strongly, because of the necessity of allowing the patient to recover from the primary shock of the hæmorrhage. It does not take into account the life of the foetus, because such a life is, in these cases, antagonistic to the life of the mother. Lastly, it has given during a period of thirty-six years a gross mortality of 5.2 per cent.

It took at least twenty years to teach obstetricians generally that the use of the vaginal plug in external accidental hæmorrhage, as taught by the Dublin school of midwifery, was both permissible and advisable. I hope it will not take another twenty years to teach them that its use in unavoidable hæmorrhage is neither the one nor the other, except under the rare conditions I have mentioned.

My object in writing this letter is mainly to prevent the views brought forward at the Edinburgh meeting from undoing any little good which my efforts may be doing to reduce the mortality from placenta previa in New Zealand. I cannot tell the proportion of fatal cases of placenta previa in this country, as the statistics do not show them. They do, however, show that one woman died out of every 2,787 labours of unavoidable hæmorrhage in the year 1920. The corresponding figures for a period of years in the Rotunda Hospital are 1 in 7,397. I believe the difference is largely due to the distance that here often separates doctor and patient, and so delays treatment. It is, however, also due to the adoption of unsuitable treatment, such as that advised at the Edinburgh meeting.

The issue which I want to put before your readers, both here and at home, is very clear. Placenta previa is always serious, and can be a fatal complication of pregnancy. Which do they prefer—a clearly defined treatment, which in thirty-six years has given a gross mortality of 5.2 per cent, or the choice between a heterogeneous treatment with a mortality of 13 per cent and Cæsarean section with a mortality of 11.5 per cent (Holland) in selected cases?

If Professor Watson can see his way to adopt the Rotunda experience of thirty-six years, and then to give the world his own experience of it, he will both improve the statistics of his hospital and materially help those whose work it is to try to reduce maternal mortality in general practice.—I am, etc.,

HENRY JELLET, M.D., F.R.C.P.I.,
Consulting Obstetrician to the Health
Department of New Zealand

Christchurch N.Z. April 9th

FOCAL SEPSIS AS A CAUSE OF NEURASTHENIA AND INSANITY

SIR,—In a letter in your issue of July 25th (p. 177) Dr Crichton-Miller has done useful service in drawing attention to four papers on focal sepsis as a cause of neurasthenia and insanity, published in your issue of July 4th. Increasing interest has in recent years been shown in this subject in this and other countries, but it may safely be said that the fringe of the subject has hardly yet been touched, and the publication of four independent yet correlated papers on this subject from the broad standpoint of general medicine and surgery in one issue of the JOURNAL is a fact of far-reaching interest and importance.

More than twenty years ago, on the strength of clinical and pathological data collected in collaboration with the late Dr George Wilson, I drew attention to the importance of this subject, and to the need for its investigation on the lines indicated in the recently published papers, but little work has yet been done on the subject. In this joint communication attention was also directed to the need for equally directing attention to the influence of chronic toxæmia in inducing impairment of function of the thyroid gland and other endocrines on the lines usefully brought out in Dr Crichton-Miller's letter. In a more recent communication it was also pointed out that the theory of focal sepsis as a cause of mental and nervous disorders was not new, it is at least a hundred years old, but little or no attention had been directed, in the light of modern knowledge, to determine its correctness or otherwise. One of the reasons for this neglect has been, it seems to me, the excessive degree of specialization characteristic of modern medical practice. There are, in relation to nervous disorders generally, hopeful indications of a reaction against this tendency, and this will be strengthened by the publication of the papers from the

Bristol school. In this connexion attention may be drawn to the view expressed by Dr P. Watson-Williams, in one of his papers referred to, that sepsis is a far deadlier foe to civilized races than tuberculosis. There is much to be said in support of this view. The time seems ripe for applying the principles of Isterism to general medicine. The successful application of these principles to surgery in the past twenty-five years has added enormously to our knowledge of disease, and greatly increased our skill in curing or alleviating it. I venture to think that the wise application of the principles of Isterism to medicine, over a similar period, would yield results of incomparably greater importance and practical value.—I am, etc.,

Edinburgh July 25th

CHALMERS WATSON, M.D.

Sir,—In drawing attention to the exacerbation of symptoms which, in a neurotic subject, may follow operative interference, Dr Crichton-Miller raises an interesting point. It is doubtful, however, whether the exacerbation is always, or even usually, attributable to a flooding with toxins.

The same phenomenon is frequently observed in cases where the operative interference has not involved any such focus. As an example I may cite three cases in women upon whom nephropexy had been performed for what was diagnosed as neurasthenia—actually all three were manic-depressives. The operation was in each of these instances followed by deterioration, and each confessed to me subsequently that her reason for submitting to operation was the hope that she might never come round from the anaesthetic. In other words, the surgeon was being used as a suicidal agent. The reason for deterioration in these cases was increased disappointment, not increased intoxication. Another neurotic, a man, who really had a septic infection of the naso-pharynx, for which he was treated by autogenous vaccine prior to operation, confessed that the reason for his increased anxiety after operation was that, the cloak upon which he had hitherto relied to cover his nervous being removed, he "felt himself more miserably than ever exposed to a cruel world." These are but a few of many similar instances with which I have met.

While quite agreeing with Dr Crichton-Miller that the physician must avoid blindness with either eye, I feel that local sepsis *per se* is not a cause of neurasthenia, but that, in these mixed cases, we have to deal with a vicious circle, the same remark applies to endocrine disturbances associated with mental aberration. It is astonishing what a burden of physical ills the robust mind can tolerate without losing its balance. The badly balanced individual, on the contrary, is easily upset by an immense variety of circumstances, and then both patient and doctor are only too willing to bring in the exerting is the essential causative factor of the breakdown, even if it has to be admitted that the sepsis is 'latent' or 'cryptogenic,' as is done by Dr P. Watson-Williams in a paper in your issue of July 4th (p. 2). In these mixed cases the real problem, in my opinion, is to decide, in any given case, which factor should be tackled first, or how far both may be treated concurrently. Perhaps some of your readers would give us the result of their experience upon this difficult aspect of the question.—I am, etc.,

Birmingham July 25th

ALFRED CARVER, M.D., D.P.M.

PLUGGING THE POSTERIOR NARES

Sir,—In your issue of July 11th (p. 60) Dr Henry S. Russell described a method of plugging the posterior nares which he believes to be new. It is by no means new, quite twenty years ago, while assisting Mr Herbert Tiller at an accessory sinus operation, I saw him plug the posterior nares in precisely the manner described by Dr Russell, and I myself on numerous occasions afterwards adopted the same method.

In the vast majority of cases of epistaxis the bleeding point is situated well forward on the cartilaginous septum, and is known to rhinologists as the "site of predilection," the bleeding can usually be stopped by firm digital pressure on the rib, using the septum as a *point d'appui*, or, better still, a plug of gauze dipped in dienealine chloride and

wring out can be inserted into the nostril, and pressure made on it in the same way (in either case the blood clot should be first cleared out). If this fact were more generally known there would be fewer occasions to plug the posterior nares.

Finally, in order to prevent recurrence, I have found the application of the galvanocautery thoroughly satisfactory.—I am, etc.,

ARTHUR J. S. ROR

Hull July 13th

Surgeon to the Throat, No. 1 and 2
Department, Hull Dispensary

Sir,—Plugging the posterior nares with a taped finger is not new, but in the hands of a skilful house-surgeon it is a method of performing this tricky operation when recognized methods are not followed. Hospital practice and private practice are not comparable. In the former everything is ready to hand, while in the latter it is frequently an ingenious operation in which special skill is required of the practitioner. Late dental extraction, it calls for mechanical aptitude. In my opinion a man who is unskilled in Lachman catheterization should not undertake the operation of plugging the posterior nares. But if he can do this, Belloc's sound, or even a suitable catheter with a small silk or gut loop, prevents the double operation of the taped finger and sinus forceps. There are a large number of cases of epistaxis in which plugging the anterior nares alone will suffice.—I am, etc.,

Southampton July 13th

JOHN FRED BIRCHOP

DISTASTES DUE TO FASHION IN CLOTHING

Sir,—It is with great interest that I have read Dr Parles Weber's communication in the *BRITISH MEDICAL JOURNAL* of May 23rd. When I was house physician at the hospital here at the beginning of the century, sufferers from chlorosis formed a considerable proportion of the women seen in the out-patient department, and the wards were seldom without one or two cases. Since the war I do not remember to have seen a single typical case in the wards, and inquiry of the house-physicians and physicians in charge of the out-patient departments has shown that it is now very uncommon there. The disease, as Dr Parles Weber points out, has practically disappeared.

But that it was the result of wearing corsets cannot be accepted unquestioned, for the following reasons:

1 The complaint was notably more common in girls of the domestic servant class—girls who, whilst they may have lived with their more fashionable sisters in the matter of tight lacing on their occasional outings, certainly did not do so whilst following their daily vocation.

2 The age incidence of a first attack of chlorosis was from 14 to 20 years. It is difficult to see why it should have been restricted to these ages if the wearing of corsets was the cause.

3 Iron, in sufficient doses, was a specific for the disease as much as quinine is a specific for malaria or mercury for syphilis. Girls who presumably continued to wear their corsets could as a rule be quickly and completely cured by the administration of iron. It is true that rest in bed was helpful in severe cases, but alone it did not cure the disease.

4 Tight lacing, especially amongst the "rather fat girls," who, as Dr Parles Weber points out, were more affected than thin girls, is by no means unknown at the present time.

5 Did tight lacing and chlorosis wane at the same time? The former went gradually, but I should have thought had gone out of fashion at least ten years before there was any noticeable diminution in the number of cases of chlorosis.

6 Whether credit for the hypothesis that chlorosis is due to tight lacing should be given to Meisner or to Rosenbach, the fact remains that it was advanced some thirty years ago and did not find general acceptance.

7 It is generally admitted and Dr Parles Weber agrees, that married life had a beneficial effect, but it would be interesting to have the verdict of a jury of

nations on his contention that, "the male once captured," women do not tire the same pains to render themselves attractive—even for the first few years of married life!—I am, etc.,

Bath July 11

RUPERT WATERHOUSE

SIR,—Dr William Elder (July 11th, p. 88) expresses his opinion that, in regard to chlorosis, "the tight corset, important as it was as a causative agent, was only one cause amongst several." The evidence that we at present possess points, I think, as I stated, to its having been the cause—that is to say, the essential cause, just as exposure to cold is the essential cause of chilblain (pernio). But though cold is the acknowledged cause of chilblain, other factors may favour its development, such as moisture, the judicious application of heat after exposure to cold, insufficient muscular exercise, certain forms of defective diet, and the age and constitutional tendency of the individual. So, in regard to chlorosis, there probably are several favouring or contributory factors—sex, age, diet, and individual constitution. The last mentioned is undoubtedly very important, the majority of girls and young women seem to have been resistant, so that with moderate tight-lacing they did not develop chlorosis. If it be asked how chlorosis, a disease known to be curable by iron, can be due to corsets, one may answer that chilblains, though known to be due to cold, can in some individuals under ordinary conditions be opposed or prevented by calcium therapy.

I am not disposed to admit without very good evidence that any disease known to the ancient Greeks and Romans was the same as what is now known by the Greek name "chlorosis." Dr Elder states that under this, its present name, it was described by Varro in 1620. One has only to go into any large picture gallery or look through any collection of prints to convince oneself that at least since 1620 tight-lacing was very prevalent amongst young women until in the present century it finally almost ceased together with the almost complete disappearance of chlorosis.

Exceptional cases might still throw valuable light on the subject, like Dr J. H. Abram's, to which I alluded in my previous letter (p. 1194). In some remarks on Dr Abram's case (Association of Physicians, May 30th), Professor W. L. Dixon said he had seen a good deal of chlorosis in Holland (particularly, he thought, in the islands), where the girls still tight-lace. I do not know whether tight-lacing is still encouraged anywhere owing to national or local costumes, but, if so, such costumes would probably be worn almost only on festive occasions, and would hardly act as a cause of chlorosis.

In my investigations of the kind the characteristic chlorosis of girls and young women, to which I have been referring, should not be confused with the so-called "secondary anaemia of the ordinary chlorotic type"—which simply means any anaemia (oligochromia rubra) due to any cause in which the colour index is below the normal—I am, etc.,

London W 1 July 11th

F PARKES WEBER

TREATMENT OF FRACTURES

SIR,—Some thirteen years ago the late Mr Clinton Dent, who was chief surgeon to the Metropolitan Police, made the statement that he had never known a police officer who had sustained a Pott's fracture return to full duty. Sir Robert Jones, in his lecture on "Crippling due to fractures," published in the *BRITISH MEDICAL JOURNAL* on May 16th, quoted this as one of his arguments to prove how badly London hospitals treated fractures. I have just returned from the discussion at the British Medical Association at Bath on our duty towards the fractured public and our duty to hospital students, and I was very sorry to hear Sir Robert repeat the same argument. It is really time that this misconception was cleared up. What Clinton Dent said thirteen years ago is about as valuable in argument as "what Gladstone said in '85." The really important fact, however, is that ever since the death of Mr Clinton Dent this statement has ceased to be true. For some time during the war I had the honour of deputizing for the present chief surgeon, Sir Charles Ballance, and I always took particular pains

to test the value of Clinton Dent's statement, which I had originally received with surprise. It took me just three months to find out that the statement no longer held true in 1915, and I believe it has become less and less accurate during the succeeding ten years. It would seem not unfair to conclude that real progress has been made in the treatment of these fractures since the original statement was made. The credit is largely due to Sir Charles Ballance, who has done so much to organize the treatment of sick police.

This may seem a trivial matter, but error is apt to grow, and it always hampers fair argument. The discussion stimulated by Sir Robert Jones has proved most interesting, and I have no doubt it will have far-reaching results. With all the wealth of argument at his disposal I hope I am not asking too much if I request him to give up this one, which is entirely played out—I am, etc.,

London, W, July 25th

JOSEPH E. ADAMS

THE DICK TEST IN SCARLET FEVER

SIR,—The following experience with the Dick test and scarlet fever antitoxin may be of interest. On January 18th scarlet fever occurred at the Ontario School for the Blind at Brantford. Between that date and January 27th six children contracted the disease. On January 27th I tested the remaining children with the intradermal test, using scarlet fever toxin from the laboratory of Dr A. Zingher of New York. Seventy-two children were Dick-negative and 38 children were Dick-positive. Between January 27th and February 19th, 7 of the Dick-positive children developed scarlet fever. On February 16th I received a supply of scarlet fever antitoxin from the Connaught Laboratories at Toronto, and injected the remaining Dick-positive children with 5 c.c.m. each, with the exception of two who had chicken-pox and who developed scarlet fever on February 19th.

The next day, February 17th, I again applied the Dick test to these children. All were now negative, with the exception of three who were only slightly positive, whereas before they had been strongly positive. On February 27th another child, who had been originally Dick-positive, had received 5 c.c.m. scarlet fever antitoxin and had then become Dick-negative, developed scarlet fever.

The epidemic then ended.

This experience would seem to prove conclusively the value of the Dick test. The scarlet fever antitoxin was, of course, used only with the idea of producing a temporary immunity. Unfortunately I was unable to go ahead with the attempt to produce permanent immunity by means of graduated doses of scarlet fever toxin in the remaining susceptible children, as the school principal felt that the children had had enough needles stuck in them. A report on this epidemic was made to the Provincial Board of Health, Ontario—I am, etc.,

THE ETIOLOGY OF MALIGNANT NEW GROWTHS

SIR,—The facts so ably discovered by Dr Gye,¹ and so widely made public, have awakened a natural enthusiasm. If the parasites grown in culture after filtration should eventually prove to be the immediate causal agents of cancer, they can be no more than a particular phase of the same protist, of which other phases are clearly indicated in the *BRITISH MEDICAL JOURNAL* of December 24th, 1882, the year in which Ivanovski demonstrated the first filterable contagium vivum, that of mosaic disease of the tobacco plant.

Anyone who will make a water culture from a ripe lesion of molluscum contagiosum in the way that I have described² will in the course of a few days have ample proof that the specific corpuscle is a protist, and, having weighed other experimental evidence, will conclude that, pounded with sand, this protist separates into variable filterable subdivisions.

No one who has not made a careful practical study of the causal organism of molluscum can have a well balanced conception of filterable micro organisms—I am, etc.,

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT]

THE Government hopes to adjourn the House of Commons for the recess on August 8th, unless industrial troubles call for debate. The chief business of this week was to take the concluding stages of the Unemployment Insurance Bill, and the House has also discussed the votes for the Colonial Office, for the Mines Department, and for the Navy's new ship building programme. Minor bills of medical interest have been advanced in both Houses. The Therapeutic Substances Bill has been read a third time in the Commons.

On July 27th the Medical Committee of the House of Commons met a deputation from the Medical Practitioners' Union on the recent refusal of the Minister of Health to hear the views of the Union with regard to panel practice. The deputation said that nine tenths of the members of the Union were insurance practitioners, but Mr. Neville Chamberlain had declared that on subjects connected with the panel he could only confer with the Panel Committees. Some members of the Parliamentary Medical Committee thought that there was much to be said for the contention of the Medical Practitioners' Union that the Panel Committees largely consisted of men to whom National Health Insurance work was only part of their practices, whereas the Union largely represented whole time insurance practitioners. The Medical Committee promised to consider the representations, and has forwarded a resolution on the matter to Mr. Neville Chamberlain.

Sir Richard Luce raised the question of the R.A.M.C., and explained the present position between the British Medical Association and the Government, which is stated in an annotation on page 224. It was understood that only two applicants for commissions had come forward at the current examinations for the R.A.M.C. The Committee determined to keep the question to the front. The War Office is reported to keep the pathetic with the claims advanced on behalf of the R.A.M.C., but there are Treasury objections to the expenditure involved, and the matter has gone to the Cabinet for decision. The Medical Committee also considered the Indian Medical Service, and was informed that changes were believed to be contemplated which would, to a large extent, remove the difficulties which stood in the way of obtaining British recruits for the service.

The Committee was informed that the estimates for the Ministry of Health were not likely to be discussed this year partly because several commissions and committees on public health topics had not reported. A discussion followed on the demand for the teaching of birth control in maternity clinics, a demand which a non-party deputation was to put before Mr. Neville Chamberlain that day. The Parliamentary Medical Committee agreed that the demand raised ethical questions more important than the medical and the general opinion of the medical members present was that there should be a thorough inquiry by departmental committee or otherwise into the implications of the proposal to give such instructions in clinics.

The third reading of the Surrey County Council Bill and the second reading of the Bethlem Hospital Bill were moved on July 28th but objection was taken to both. Dr. Fiemantle had given notice of opposition to the Surrey County Council Bill in regard to a clause in which the county virtually resigned to the medical officers of urban districts the inspection of maternity homes in such areas. Dr. Haden Guest gave notice of opposition to the Bethlem Hospital Bill on the ground that part of the site of the hospital should be reserved as an open space.

Therapeutic Substances Bill

In Committee on the Therapeutic Substances Bill Commander Keworth said that the bill was to apply to therapeutic substances specified in the schedule and also to any other therapeutic substances which might be added to the schedule by regulations. He thought that the power of adding to the schedule by regulations if given to Government departments was liable to abuse and asked why the Ministry of Health did not put in a complete list of the chemicals which it proposed to control. Sir Kingsley Wood said it would be unwise to bring in a new bill for every new remedy that might be discovered. All regulations that would give adequate protection. He did not think however that Parliament would be anxious to interfere in a matter in which the Ministry of Health had been largely guided by the Medical Council. The bill was founded on a recommendation from the appropriate branch of the League of Nations which had found that it was necessary in dealing with these substances that in all countries proper regulations should be laid down. British standards in respect of chemicals were very high but it was only fair to those who were manufacturing the substances up to the proper standard that they should be protected.

Dr. Drummond Shiels strongly supported keeping the bill open for the possible addition of other substances. He thought there were omissions in the schedule as it stood and pointed out that the United States Pharmacopoeia required criminal indications and its preparations to be standardized.

The clause was added to the bill as it was that imposing restrictions on the importation of therapeutic substances. In the clause moved to leave out Commissioners of Customs and Excise and to insert instead Licensing Authority. This change was in accordance with representations from the Medical Practitioners' Union that the substances should not be tested by the Commissioners of Customs and Excise but by the Licensing Authority to be established by the bill. The authority would have the assistance of Dr. Watts who had had a similar amendment down and allowed to pass without effect. If the clause were in a few months to obtain in large quantities from Mr. Herbert Williams a list of the substances which they hoped to import.

Dr. Watts who had had a similar amendment down and allowed to pass without effect. If the clause were in a few months to obtain in large quantities from Mr. Herbert Williams a list of the substances which they hoped to import. Sir Kingsley Wood then moved an amendment to make it clear that in the case of a foreign serum which was not manufactured in this country it must conform to such standards of strength and purity as might be prescribed or if there were no such standard it must conform to the regulations on quality and purity which applied to substances of the same class. Any Spahlinger serum imported would be required to conform to such regulations in regard to quality and purity as applied to such Spahlinger serum was prepared from toxic constituents. If the proper care in its preparation might be contaminated by anthrax tests to be used by a number of practitioners throughout the country. He was anxious that no substance should be prevented from being properly tested in this country should be prevented by terms of a suggested alternative amendment. He read out the amendment met Dr. Shiels's case. The whole object of the bill would go if the examination of a therapeutic substance could be avoided by sending it to a medical practitioner. But another objection declared that nothing in the bill should apply to the preparation by a medical practitioner for and at the request of applied if prepared for an individual patient. He thought the medical practitioners of the country were satisfied with the proviso. On this assurance the amendment proposed by Sir Kingsley Wood was accepted.

On the clause dealing with the constitution of the Joint Advisory Committee Sir Kingsley Wood moved to add, "no member appointed by the British Medical Association." He said he moved this in response to the suggestion that medical practitioners generally should have some representation on this body. The British Medical Association covered all parts of the kingdom and was representative. The addition would add to the strength of the committee and the Government gladly responded to the suggestion. Dr. Watts moved to add also one member appointed by the Royal College of Surgeons of England and one appointed by the Royal College of Physicians of London. He said he could not understand why the Council of the Pharmaceutical Society or the Council of the Institute of Chemical Engineers could not be represented by the Council of the Pharmaceutical Society. Sir Kingsley Wood said he thought most members would agree that it was helpful for a representative of the Pharmaceutical Society to be engaged on an inquiry of this kind. He could not accept Dr. Watts's amendment because if he did so he would immediately be confronted by suggestions from Scotland and possibly from Northern Ireland which would make the Advisory Committee unmanageable.

The amendment was negatived. Sir Kingsley Wood then accepted an amendment to the clause dealing with power to make regulations. He declared that regulations made by the Minister should be modified or annulled if after twenty-one days praying for such a change the House of Parliament without further change. On July 28th in the House of Lords the Commons amendment to the Therapeutic Substances Bill were considered. On the motion of Viscount Gize all the amendments were accepted with a slight modification to that which provided that a regulation should be modified or annulled following the voting of an address by either House of Parliament.

Diseases of Animals Bill

On July 28th the House of Commons read the Diseases of Animals Bill a third time. Previously on the report stage Mr. Alexander had renewed his protest against the use for human food of any part of the carcasses of animals slaughtered as tuberculous.

culous. He moved an amendment to provide that compensation should only be paid when no part of the slaughtered animal was so used. He was afraid that often the hind parts of a tuberculous carcass were sold for making up such dishes as sausages for sale at a cheap price. There was no provision for protection against the use of the blood from the animal. In slaughterhouses the blood from the various beasts mingled in one vessel and was used for food purposes. Through all the agencies, national local and voluntary £12 000 000 to £14 000 000 a year was paid in trying to cure tuberculosis. By the bill £67 500 a year was being voted for its prevention more money should be devoted to that purpose.

Mr Buchanan said that in Scotland as in England the blood of animals was more and more used in the preparation of food.

The Minister of Agriculture Mr Wood said the animals that would be slaughtered as tuberculous under the bill were only a portion of the tuberculous carcasses discovered after slaughter to be diseased. After consultation with the Ministry of Health he was entitled to say that both scientific and medical opinion the world over held that the total condemnation of a carcass on evidence of local tuberculosis was needless and wasteful. Both Holland and Denmark followed the same practice as this country. He would go some way, however, to meet Mr Alexander and would promise to issue an amendment to the Tuberculosis Order providing that the local authority's inspector, when acting under the Order, should send a notice in writing to the medical officer of health of his intention to slaughter an animal under the Order, giving time and place and that the veterinary officer should not remove the carcass or offal from the premises until he had received from the medical officer of health a certificate saying whether the carcass or any part of it might be disposed of for human consumption.

Dr Shells in supporting Mr Alexander's amendment said that with a local tuberculous lesion there might be a lymphatic spread of undetermined extent and it was difficult to delimit the exact portion which might be used for human food. In a cow with tuberculosis of the udder there would certainly be secondary infection and toxic absorption. The thorough cooking of meat was a great safeguard but sausages were often cooked very superficially and minced meat—a kind universally used—was often very lightly cooked. Vendors sending animals for slaughter, when doubtful about the meat often avoided the large towns. He urged the Minister to carry on the work of ridding the country of tuberculosis a great part of which, varying from 35 to 50 per cent of all cases of bovine tuberculosis was due to the bovine tubercle.

Sir Richard Luce thought that Dr Shells had perhaps given an exaggerated view of the danger of tubercle. There was a large consensus of opinion in the medical profession which held that there was practically no danger in the use of a large portion of the carcasses of animals infected only by local tuberculous disease. In such cases there was practically no risk of blood infection. Some years ago a Royal Commission had decided there was no danger in the great majority of cases.

Answering an observation by Mr Palin the Minister of Agriculture said that under the existing Order no part of the carcass of an animal which had tuberculosis with emaciation was allowed to pass for human consumption. Mr Palin retorted that there were people who traded in this suspicious meat.

Dr Vernon Davies said that if members were to take up the attitude that if the blood stream carried certain toxins then the carcass should be destroyed they were opening a big question. It would mean that an animal could not be killed for human consumption unless it had a clean bill of health. Few animals in the country could pass such a test.

Mr Alexander, in view of the assurance given by Mr Wood, withdrew his amendment.

In an answer given later, the Minister of Health stated that having considered the question of the slaughter of animals for human consumption, he did not think that any useful purpose would be served by setting up a committee of experts to hold an inquiry into the question.

Insurance Contributions Anticipated Surplus

On the third reading of the Contributory Pensions Bill Sir Robert Horne renewed his suggestion that the Government should reduce the National Health Insurance contributions of employer and employee by a penny each per week. He estimated that the quinquennial investigation now finishing would reveal £60 000 000 available for the reserves which the actuaries desired and that something like £40 000 000 of surplus would be declared by the various approved societies. He contended that the reduction which he proposed in contributions would still leave the fund solvent and yield surpluses for extra benefits.

Mr Neville Chamberlain said that until the report of the Royal Commission on National Health Insurance had been received the Ministry of Health was not in a position to say what surplus was likely or whether there would be any surplus at all. It was therefore impossible to contemplate at present any reduction in the rate of contributions. Certain rather disquieting features of which the Ministry of Health had information made it very unlikely that in future quinquennial periods the surpluses would be anything like what they had been. At present the annual charge of about £2,000 000 for doctors and drugs was being paid from an accumulated balance but when that balance came to an end in 1926 the charge of £2,000 000 would then fall on the contributions. Even if other factors remained the same a year later the charge would be reduced thereby to £3 000 000. Rather disquieting features arose out of the rate of dismissal unemployment benefit and the existence of so much unemployment meant a reduction in contribution surplus which would have its effect upon the gross surplus.

The Contributory Pensions Bill was then read a third time without a division.

Tropical Medicine

Mr Omsby Gore Under Secretary for Colonial Affairs replying on the debate on the Colonial Office vote in the House of Commons on July 21st referred to the importance of medical research in the overseas Dominions, it was the doctor as much as the engineer that made Panama. The most urgent thing, certainly as regarded the development of all tropical countries—tropical Australia as well as tropical Africa—was the further work in the combating of tropical disease, and in working out of all the various problems connected with the life of the different races in tropical Dominions. It was he said a fallacy to suppose that it was only the white man who found it difficult to live in the tropics. In East Africa the birth rate was extremely high but the infant mortality was appalling. So far as he could get figures—and it was very difficult to do so in connexion with tropical administration because no adequate staff or statistics existed—in many of the native areas and districts remote from civilized life the mortality in the first year of life was anything from 400 to 500 per 1 000 children born. In facing these questions great care should be taken to be thoroughly objective to be thoroughly determined to face the facts to do the best possible to make the thing work to help and not to cramp. Constructive effort was equally needed in West and East Africa. He hoped shortly to visit West Africa. He was convinced that the progress of the negro races of Africa was bound up with their ability and their increasing ability to make use of the enormous resources of the country in which they lived. It was only by then becoming physically mentally and morally more capable of doing that that they would progress to a higher civilization of their own.

Several of the previous speakers referred to the need for medical work and medical research in the tropics. Mr Thomas urged that attention should be given to combating venereal disease. Mr Lunn recounted the work of the Liverpool School of Tropical Medicine and hoped the Colonial Office would make more use of its services.

Spahlinger Treatment for Tuberculosis—The group of medical members of Parliament who have been negotiating with M. Spahlinger announce that his arrangements with the Bovine Tuberculosis Committee at Crewe for a test of his vaccine for bovine tuberculosis on animals are practically complete. All his energies will be required for three months in preparation for this test. He will then be free to proceed at once with the completion of his twenty-two serums and vaccines for the cure and immunization of human beings and will devote himself and his staff at Geneva to the production of these of which about one third are now in existence. Unofficially it is added that M. Spahlinger has given this group of medical members of Parliament a written assurance that he will provide the serums and vaccines for human tuberculosis in sufficient quantities if funds are provided and it is understood that these will be forthcoming. The test of the products if made would be in England, and it is possible that the serums and vaccines may be produced here under supervision.

Health of School Children—In Committee of the whole House on the Board of Education estimates Mr H. A. L. Fisher asked whether the reports received by the Board of Education from its inspectors about the health of children in the schools were satisfactory. Had the improvement in the years immediately preceding and during the war been maintained? Very largely owing to the skill, energy and devotion of the school medical services the health of the school population had been greatly improved but there were still great defects to be remedied. The last report of the Board of Education stated that 200 000 mentally or physically defective children had not been given places in special schools. Owing to the great expense of special schools this deficiency could not be made up immediately but he hoped that education authorities might receive aid from private benefactors to this end. Dr Haden Guest said he would like to see all schools including private schools inspected by inspectors of the Board of Education not only from the educational point of view but medically. At present the physical health and well-being of the child in the elementary school was in some respects better looked after than that of the child in certain public schools. By purely administrative means the Board of Education could extend its inspection to all schools. He maintained that, judged by records of weight, height and growth 10 per cent of the children attending elementary schools were not adequately fed. It should be the business of the medical officer and the school inspector of each school to make a list of children who would benefit by increased nourishment and it ought to be part of the school curriculum to provide school meals which could either be paid for or given free for all the children in the school who were not getting the amount of food required. Dr Graham Little drew attention to what he thought the meagre provision in the estimates for the needs of the University of London but the Deputy Chairman pointed out that this arose on another vote. The Duchess of Athol, Parliamentary Secretary Board of Education said that in 1923 it was found that 36.7 per cent of the children in the schools inspected had defects of one kind or another, compared with 44 per cent in 1894. In the same year there were 5.9 per cent who had been diagnosed as undernourished as compared with 12.8 per cent in 1913. The number of children suffering from defective hearing was only half of that ten years ago. Local authorities were well aware of their duty of providing meals for necessitous children and the Board had been pressing for the provision of meals at school canteens for non-necessitous children especially where the children had to go two or three miles to school. The estimate of £25,652,754 for the Board of Education was approved.

Mental Deficiency—On July 27th Mr Hurd who asked what official expert investigation into the effect of mental deficiency upon the national life was now in progress was told by Sir Kingsley Wood that the Board of Control in conjunction with the Board of Education was about to undertake an inquiry into the incidence of mental deficiency. An inspector of the Board of Control had been detailed to carry out the investigation. It was estimated that the inquiry would take at least a year to complete and it was not anticipated that any report would be available before that time.

General Nursing Council—The Select Committee on the General Nursing Council has sat twice to hear witnesses. After taking evidence on July 28th the Committee sat again on the following day to prepare its report. It has still to take evidence from witnesses now abroad but hopes to report before the next session. Witnesses already heard include Mr J. G. Brael, C.B. (Ministry of Health), Sir Wilmot Herringham (Chairman of the General Nursing Council), Mrs Bedford Leach (Member of the Council), Mrs Herbert (sister tutor St George's in the 1st), Miss Haywood (Waltham town), Miss Philpott (High Wycombe), Miss Lucy Grant Duff (Herbert Paterson C.B.I. (medical honorary secretary of the B.N.A.), Miss Maud McCallum (honorary secretary Professional Union of Trained Nurses) and Miss Du Sautoy (member of the General Nursing Council).

Poison Gas—On July 27th Mr Austen Chamberlain Foreign Secretary told Colonel England that at the Arms Traffic Conference at Geneva last May under the auspices of the League of Nations a protocol was drawn up prohibiting the use of chemical or bacteriological methods of warfare. Twenty-five States had signed the protocol which remained open for accession by other Powers. It would come into force immediately on ratification by between those States which had ratified. On July 28th Sir L. Worthington Evans informed Mr Thurtle that poison gas was being manufactured only on a very small scale for experimental purposes.

Training in Cleanliness—On July 27th Sir C. Oman asked the Minister of Health whether considering the high importance of perfect cleanliness in casual wards both to the public and to the inmates of the wards he would authorize the insertion of eight hours work in washing, scrubbing and cleaning as one of the alternative prescribed tasks for inmates passing through such wards. Mr Neville Chamberlain replied that he was prepared to consider any application made by a board of guardians in this sense and had already approved a task of this kind in eight cases.

Food Preservatives—Sir Kingsley Wood informed Mr Clynes on July 28th that the recommendations of the Departmental Committee on Food Preservatives had in view that the use of preservatives could be avoided partly by the adoption of greater care including more cleanly methods in the preparation, transport and distribution of food and partly by the increased use of cold storage. A large amount of cold storage in the country was not being used. The Minister of Health recognized that adequate accommodation was not available everywhere but anticipated that the prospect of restrictions on the use of chemical preservatives would result in the increased use of the existing accommodation and the provision of such further accommodation as might be necessary. This was one of the reasons for allowing an interval before the regulations became operative. Every opportunity had been given to the trades affected to present their views on the proposed regulations. Mr Chamberlain in an answer to Mr Lowth said the trade opposition to the prohibition of preservatives in food had in some cases taken the form of an allegation that the prohibition would increase the cost of the food. It was impossible definitely to prove or rebut this but he did not think that there was adequate ground for supposing that the prohibition of preservatives would cause an increase in prices if a sufficient period was allowed for the changes. Replying to Mr Sutton Mr Chamberlain said the physiological effect of the use of preservatives in food was considered by the recent Departmental Committee on Preservatives and Colouring Matters in Food which included distinguished physiologists in no way connected with the Government or the trades concerned. He had an offer from one large firm interested in the production of boron compounds to co-operate in a further inquiry into the effect of the consumption of small quantities of such compounds in human food but he did not think it necessary to institute any further inquiry.

Tuberculosis in Service Pensioners—The Parliamentary Secretary to the Ministry of Pensions has stated in reply to questions that the earlier records of the Pensions Ministry did not distinguish pulmonary tuberculosis from other chest complaints. During the last five and a half years however approximately 14,000 cases had been admitted to compensation in respect of disablement arising from this disease. The number of men in receipt of pensions for pulmonary tuberculosis at the present time was approximately 36,500. About 10,000 men were in receipt of pensions at the rate of 100 per cent in respect of total disablement due to pulmonary tuberculosis but how many of these fell under the special arrangements for men who had completed a course of sanatorium treatment could not be stated.

Notes in Brief

The Voluntary Hospitals Commission is understood to have tendered its report.

Though no date has been fixed for the constitution of the Indian Public Services Commission it will be set up without avoidable delay.

The Committee on Child Adoption has presented to Parliament a further report containing suggestions for a draft bill. The Dangerous Drugs Bill was read a second time in the House of Lords on July 28th.

Obituary

HARRY DRINKWATER, M.D., M.Sc. (Hon.),
Wrexham

We regret to record the death of Dr Harry Drinkwater at his residence in Wrexham, on July 11th. He was 70 years of age and received his medical education in Durham and Edinburgh. He took the diploma M.R.C.S. Eng. in 1877 and graduated M.B., C.M. in the same year. When he became M.D. in 1885 he was awarded a gold medal. In 1924 he received the honorary degree of M.Sc. from the University of Wales. After practising in Sunderland for a short time he entered into partnership with the late Dr Lyton Jones at Wrexham, where he continued to practise until his death. He was president of the North Wales Branch of the British Medical Association from 1917 to 1922, and was a justice of the peace for the borough of Wrexham.

Dr Drinkwater possessed considerable artistic ability, and the National Museum in Cardiff contains many botanical drawings by him. He contributed numerous papers to various societies, and was the author of *A Primer of Dietetics*, and also of *Fifty Years of Medical Progress 1877-1922*, published in 1924. For the last twenty years he had been engaged in compiling a medical biography. Dr Drinkwater first married Miss Ellen Percella Reed who died in 1901 leaving three children, one of whom, Dr H. Drinkwater, is a specialist to several London hospitals. Dr Drinkwater's second wife, who is a medical graduate, was one of the first women to take the D.P.H. degree in Liverpool, and was awarded the O.B.L. for her services at the Hospital for Military Invalids in Malta during the war. She is a justice of the peace for the county of Denbigh.

A colleague writes: By the death of Dr Harry Drinkwater North Wales has lost one of its oldest and most respected medical practitioners. He had not been in good health for some considerable time, but was in fairly active practice until the day of his death which was brought about by an attack of angina pectoris. Many in Wrexham will have lost a true friend and helper. He was always a student and a great reader and thinker, one of the most methodical men that I ever knew. He was one might say, wedded to his profession, and a continual source of inspiration to his young colleagues, trying to instil into them the value of reading, methodical examination of patients, and the collecting of cases, rare and common, upon which to build priceless information which would yield great results in practice. This he always did throughout his life, and the variety and originality of his communications to learned societies will always be a source of amusement to his friends. He was a prolific writer, and could always be depended upon to read interesting papers at the local meetings. He would not accept any statement without sifting the facts, yet he was not dogmatic in his own statements. He was the embodiment of professional etiquette and an example to all. One of his favourite sayings was "Scepticism is the highest virtue and blind faith the one unpardonable sin." It is not for his profound knowledge of his profession that Dr Drinkwater will be remembered by his colleagues, but for his kindly nature, his deep sympathy, and cheerful outlook upon life. He was laid to rest on a beautiful sunny afternoon, surrounded by a host of friends, and amidst a wealth of the flowers that he loved so well.

HAROLD CLIFFORD, M.B., F.R.C.S. Edin.,
Surgeon to St Mary's Hospitals Manchester; Surgeon for Women
Salford Royal Hospital

The death of Dr Harold Clifford came as a great shock to his numerous friends. It is true that his health had not been good for some three or four years, but there had been nothing very definite. In April last he had a sudden loss of vision, which was due to an intracranial haemorrhage. But towards the end of June his eyesight had shown much improvement, his general health was better, and he was in good spirits—he had even arranged to leave for South America for a voyage on July 9th. On July 5th he became ill with what appeared to be a gastric disturbance. Late

on July 6th he became restless, and he died early on Tuesday morning July 7th, from a severe cerebral haemorrhage.

Dr Clifford was well known in Manchester and occupied many important posts. He received his medical education at University College Hospital, London, and graduated M.B. Lond. in 1899, and took the diploma of I.R.C.S.I. in 1905. In 1901 he was appointed resident obstetric house-surgeon to St Mary's Hospital, Manchester. He had previously been house physician at University College Hospital, and medical officer to the cancer wing of the Middlesex Hospital. His progress in Manchester was steady, in 1912 he became assistant surgeon and in 1919 surgeon to St Mary's Hospital. He was at one time surgeon to the Northern Hospital for Women and Children, Manchester, and latterly surgeon for women to the Salford Royal Hospital. He was also a lecturer on clinical obstetrics in the University of Manchester. He was a member of the North of England Obstetrical and Gynaecological Society for many years, and held the office of president in 1922. He was widely known as a wise adviser and a skilful surgeon in his own department, and had a large practice.

Dr Clifford was handicapped for the struggle of life by ill health. A delicate infancy left him with rather a poor physique, but he had in him a very active brain, keen judgment, and a cheerful and genial disposition. He gave an example of what could be accomplished by a courageous and resolute spirit in a frail body. He was never fitted for any form of severe physical exercise, and the recreation of outdoor games or any kind of sport was barred to him. It was his lack of stamina which determined his mode of life, and yet one wonders whether, if his lot had been cast in healthier surroundings, he might not have been stronger. As it was, he was content with the life of a town dweller. He was a bachelor and lived in the centre of the city. He found his pleasure in his work during the day, and in reading and in the society of his friends in the evening. He had a charm of personality which brought him many friends and endeared him to his patients. He was an excellent host and seemed to be happiest when he was entertaining a small circle of friends. His manner was always quiet, and he had a keen sense of humour.

Although he held so many important appointments and had attained to a position of distinction in his special department he never sought publicity—on the contrary he did all in his power to avoid it, and preferred to remain in the background. His death has been keenly felt by all who knew him well, and he will be much missed by a large circle of friends and, perhaps most of all, by his colleagues.

A. D.

ROBERT MILNE BEATON, M.B., C.M.,

Late Chairman London Water Examination Committee

We much regret to record the death of Dr. Robert Milne Beaton at his residence in Highbury, on July 21st at the age of 71. Dr. Beaton received his medical education at Aberdeen and Guy's Hospital, graduating M.B., C.M. in 1883. He was a member of the Council of the British Medical Association from 1912 to 1914, a member of the Executive Committee of the St. Pancras and Islington Division from 1911 to 1912, chairman in 1915, and representative from 1913 to 1916. He was a member of the Executive Committee of the City Division in 1919 and 1920. He took a very active part in the National Insurance controversy of 1911-13, and his eloquence, combined with his evident sincerity, made him a very great influence in the Representative Body and Council as well as in his Division.

Sir Alexander Houston writes

On July 25th at Hampstead Cemetery I had the mournful privilege of paying a last tribute of respect to the memory of my dear old friend, Dr. Robert Milne Beaton.

Dr. Beaton was the first chairman of the Water Examination Committee of the Metropolitan Water Board and Londoners owe him a deep debt of gratitude for the enthusiastic way in which he threw himself into the task of securing the safety of the supply to the metropolis. He served seventeen years on that committee (seven as chairman), and the splendid work he did will never be forgotten. Dr. Beaton was the staunchest advocate of purity, and at

heart probably cherished the hope of a revival of the so-called London County Council Welsh Water Scheme. At all events he never tired of saying, "I want clean water, not cleaned water." Failing the provision of a virgin source of supply, he threw himself heart and soul into the task of perfecting purification safeguards. There can be no shadow of doubt that Dr. Beaton's influence is still felt in the affairs of the Board. His hatred of sham and subterfuges, his suspicion of compromises, his passionate love of truth, and the transparent honesty of his motives were bound to influence all those with whom he came into contact.

Some of the other positions held by him were Representative of the St. Pancras Borough Council, 1903-6; representative of the London County Council, 1906-22; member of the Works and Stores Committee, 1904-5, and June, 1911, to May, 1922; Finance Committee, June, 1907, to June, 1913; General Purposes Committee, 1910-13, and (as already stated) Water Examination Committee, June, 1905, to June, 1922 (Metropolitan Water Board).

Dr. Beaton had a breezy personality, he was bubbling over with good humour, and his smile and laugh were infectious and well-nigh irresistible. The kindness of his heart was proverbial, and his goodness to the poor widely known. He will be sorely missed, by no one more deeply and sincerely than his old friend and admirer who sorrowfully writes these notes.

A. BLAYNEY, F.R.C.S.I.,

Surgeon to the Mater Misericordiae Hospital, Assistant Professor of Surgery, University College (N.U.I.)

We regret to announce the death of Mr. A. J. McEuley Blayney, surgeon to the Mater Misericordiae Hospital, Dublin. For some time past Mr. Blayney had been residing at Howth to convalesce from an attack of influenza. He came into Dublin every day, however, and attended to his extensive practice. A keen golfer, he was walking across the Portmarnock links with his family, when he was seen to stumble and fall. Dr. Cecil Robinson, who happened to be playing close by at the time, hurried to his assistance, but, in spite of all his efforts, Mr. Blayney never recovered consciousness. There was an immediate cessation of all the matches that were being played on the links, and the body was subsequently removed in an ambulance to 15, Merion Square, Dublin. Mr. Blayney was a frequent visitor to the grounds of the Portmarnock Club, and was a member of the committee, and it was his great interest in golf which had brought him to the links although he was not playing himself. The deceased surgeon leaves a widow and four children. Mr. Blayney was the son of Mr. Alexander Blayney, a ship owner, of Cushendall, co. Antrim, and was born in 1869. After a distinguished career at St. Malachy's College, Belfast, he went to the Catholic University, Dublin, where it was early seen that his natural bent was in the direction of surgery. After a brilliant academic career he took the M.B. and M.A. degrees, and subsequently became a Fellow of the Royal College of Surgeons. He had been surgeon to the Mater Misericordiae Hospital, a position which he held for many years, he was extern examiner in surgery at Dublin University and an examiner in biology at the Royal College of Surgeons, Ireland, and he also acted for a time as an examiner in surgery for the same body. He had been professor of biology and assistant professor of surgery at University College, Dublin, since 1909, and was visiting surgeon to Marinooth College, Blayney, with all his professional training and vast surgical experience, did not contribute as much as might be expected to the literature of surgery. This was due almost entirely to the fact that when he had done his teaching and operative work there remained for him no time for writing. Amongst his contributions to the BRITISH MEDICAL JOURNAL were "Removals of great length of intestine" and "Four cases of removal of Grasserian ganglion for epileptiform neuralgia." He was for many years a member of the Council of the Royal College of Surgeons in Ireland and his election for the presidency at an early date was assured. He was also a member of the British Medical Association. During the great war he served in France, where he did excellent work.

We regret to have to record the death, on July 27th, after a long illness, of Mr. WILLIAM NEWTON SHANNON, who for some ten years had acted as Parliamentary Correspondent of the *British Medical Journal*. He was born at Mistley, Essex, and received his early training with the *East Anglian Daily Times*. In 1897 he was appointed Lohia correspondent of the National Press Agency, and eight years later succeeded Sir Arthur Spurgeon as editor of the Agency. Afterwards he became a partner in the Central Press Agency. He had many friends both within and without the profession of journalism, and for nearly twenty years was honorary secretary of the Whitefriars Club, in which he took a great interest. He had recently been concerned in the appeal of the Westminster Hospital for funds to reconstitute the fabric, for these services he received the thanks of the committee and was made a governor of the hospital. He showed great interest in his work for this journal, and on several occasions gave the Association the advantage of his wide acquaintance with parliamentary procedure.

Medico-Legal.

CLAIM AGAINST A MEDICAL MAN WITHDRAWN

The claim of James Higgins, an employee in the tramway department of the Manchester Corporation against Dr. R. G. Clements (Manchester) for alleged negligent treatment was withdrawn before the conclusion of the defendants' case at Manchester Assizes on July 15th. Mr. Justice Fraser, in directing the jury to return a verdict for the defendant with costs, said that there was not the slightest foundation for any suggestion of negligence against the defendant.

Mr. N. J. Laski and Mr. Barry appeared for the plaintiff and Mr. T. Eastham, K.C. and Viscount Keregh for the defendant.

The plaintiff's case was that in March 1922 Dr. Clements certified him to be suffering from rheumatoid arthritis and conjunctivitis and in January 1924 he consulted the doctor again but did not mention his eyes until February 12th. On February 15th Dr. Clements noted that the rheumatic pains had gone but that the eyes were worse examination showing phlogia conjunctivitis, choroiditis and ulceration. When Higgins walked into the surgery Dr. Clements asked him what was the matter with his eyes and Higgins replied, "I am not bothering about my eyes. I can see as well as ever but the pain in my back is very bad and almost stops me from walking." Dr. Clements looked at the plaintiff's eyes and his assistant Dr. Scott put him in a chair, put one hand on his shoulder and took a little brush and flicked something from a box into the plaintiff's right eye. The pain was instantaneus and intense and Higgins screamed in agony. The alleged consequence of the administration of the powder was that the plaintiff's eyesight was so damaged that he could no longer follow his former employment and he was now engaged by the corporation to take charge of a small telephone switchboard—a job ordinarily done by a boy. On February 28th Dr. Clements made a note thatritis had developed and the following day Higgins was admitted to hospital where he was treated by Dr. Ware.

For the defence a number of eye specialists were called who all agreed that it was not within the bounds of possibility that the condition of the plaintiff could have been caused by the calomel treatment administered by the defendant. The inflammation was entirely due to the presence in the plaintiff's body of a focus of poisoning which affected different parts of his body at different times. This accounted for the variations in the plaintiff's vision that had been noted and which were in no sense unusual. In every respect the case was a normal one.

Before the medical evidence for the defence was completed plaintiff's counsel and Dr. Clements's professional career was the issue in the case and every regard should be had to that. The plaintiff was satisfied that he no longer had a case and therefore no hazard should be allowed to intervene. The plaintiff withdrew every aspersion of any kind against the competence of the defendant. The proceedings had been brought under a misconception of the facts and they were now satisfied that no blame attached to Dr. Clements.

DAMAGES FOR DEATH DUE TO MOTOR COLLISION

In an action in the King's Bench Division before Mr. Justice Avey and a special jury on July 17th damages to the total amount of £12,000 were awarded to the widow of Dr. C. J. Pentland and her two sons. Dr. Pentland had practised in Ireland but in 1920 he acquired a practice in Gower Street paying £2,000 for the house and practice and spending a further sum of £2,000 on the property. For the last four years his income was £2,000 a year. On December 21st 1924 Dr. Pentland was killed while standing on the doorstep of his house in Gower Street by a motor lorry belonging to Messrs. Dewhurst butchers and a motor car owned by Messrs. Cleeve blouse manufacturers Great Portland Street coming in collision. Dr. Pentland was crushed against the wall and killed instantly. His practice had since been sold for £3,600. The jury found that the death of Dr. Pentland was due to the negligence of both defendants and awarded the widow £8,000 and the children £2,000 each the latter sums to be paid into court and invested by the Master on the children's behalf.

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on July 25th the following medical degrees were conferred:

B.M.—P. B. Boardman 1 C. Whitchall Cooke T. I. Lyves C. L. Tolst.

UNIVERSITY OF LONDON

A meeting of the Senate was held on July 22nd the Vice-Chancellor (Professor J. A. Gardner Litt D) being in the chair. The title of Reader in Medical Radiology in the University was conferred on Mr. J. C. Thomson M.A. M.B. Ch.B. F.R.C.S. in respect of the post held by him at the London School of Hygiene and Tropical Medicine.

The Committee of the Medical Members of the Senate have elected Sir Wilfrid P. Herrington, M.A. M.D., F.R.C.P. to be the chairman for the year 1925-26.

June Matriculation

At the June matriculation examination of the University of London there were 116 successful candidates in the first division and 919 in the second division. In addition supplementary certificates were gained by 52 candidates in Latin 3 in mathematics (more advanced) 2 in chemistry 1 in heat light and sound and 1 in Spanish. Six candidates took the junior certificate in English.

UNIVERSITY COLLEGE

The following awards have been made in the Faculty of Medical Sciences:

Cliff Memorial Prize for proficiency in anatomy physiology pharmacology and chemistry R. M. Barrett
Gold medal for anatomy (senior class) Mary J. Sharp
Histology and embryology (prize equivalent to silver medal) Andrew Z. Belcher and Margaret D. Wright (equal)
Silver medal for organic and applied chemistry (general course) D. I. Osborn
Gold medal for physiology (senior class) T. R. Innes
Silver medal for pharmacology (general course) H. L. James

UNIVERSITY OF EDINBURGH

A GRADUATION ceremony was held in the M. J. Hall on July 24th. The following degrees were conferred:

M.D.—A. Barlow (E. Hunter S. C. Clatter L. S. I. Davidson (an absent) H. B. Dicks R. N. Gibson
Torrairie K. A. J. Martin S. I. Bown S. (an absent) May D. Straker B. C.

Ch.M.—T. B. Mount
I.D.—Dr. I. Dautchando for thesis on "The acid base equilibrium of the blood in electrolytic states."

TERRITORIAL DECORATION

The Territorial Decoration has been awarded to the following officers of the R.A.M.C. (1st) Tulent Colonel (Brevet Colonel) G. C. L. Simpson, O.B.E. and Majors A. A. Hingston and S. F. Linton.

Medical News.

THE sixth annual report of the Ministry of Health for the year ended March 31st, 1925, has been published by the Stationery Office and can be obtained through any bookseller (price 3s 6d). It deals, among other matters, with finance, Poor Law, and housing and town planning.

The council of the Institution of Electrical Engineers, which took a part in founding the Society of Radiographers in 1920, and has up to now nominated six out of the eighteen members of the society's council, has withdrawn its nominees and terminated the institution's connexion with the society. The council of the institution informs us that it has taken this action because the majority of the council of the Society of Radiographers have resolved upon certain alterations of the society's articles, with which the council of the institution is in disagreement as in the council's opinion these alterations will materially lower the professional status of non medically qualified radiographers.

The Fellowship of Medicine announces a special series of lectures on tuberculosis from October to December. From August 24th to September 5th there will be an intensive course in general medicine, surgery, and the special departments, with practical study in gynaecology and obstetrics, at the Queen Mary's Hospital, St. Mary's. The Serenus Hospital will hold an operative surgery course from September 7th onwards, and classes will be held four times weekly. The Brompton Hospital has arranged a course in pulmonary diseases from September 21st to October 3rd. There will be afternoon courses at the Brickfields Skin Hospital and the Infants Hospital from September 7th to 19th. At the Royal Westminster Hospital a course in eye diseases will be given from September 7th to 26th and an intensive course at the Westminster Hospital in general medicine and the specialties is announced for

THE climatological congress at Davos from August 16th to 22nd, will be divided into three main sections—a physico-meteorological, a biological, and a clinical. The subjects to be dealt with include the effect of climate on various diseases, the climatology of high mountains and the marine climates of Naples and of Holland. Professor Leonard Hill will give an address on the influence of sunshine and open air on health, and Sir Henry Gairdner will compare the effects of inland and marine treatment of surgical tuberculosis. Other subjects to be considered include heliotherapy in surgical diseases, adaptation to climate and to work on the high

mountains during the period of semile involution and the significance of the ozone in the atmosphere in relation to solar radiation

The *Gesundheitsfürsorge für das Kindesalter* is a new German periodical devoted to infant welfare. About eight numbers are to appear yearly at the price of 20 marks. The editors are Professors L. Dietrich and P. Pott of Berlin. The first number contains original articles by Professor von Pfander on clinical medicine and child welfare, by Professor Leo Langstein, on the problem of children's milk, by Professor Pott, on the mortality in the first seven days of life and on infant welfare schemes. The titles of recent articles of pediatric interest in German literature are given

THE new bacteriological and biochemical department of the Harrogate Royal Bath Hospital will be opened by Princess Mary, Viscountess Loxelles on Monday August 10th. The Earl of Harewood will take the chair at 3.30 p.m.

THE Ministry of Health has issued a revised list of approved sanatoriums and other residential institutions for the treatment of tuberculosis in England and Wales. It is published by H.M. Stationery Office, price 2d net.

THE Dunlop Rubber Company Ltd (Kingsway, London, W C), has prepared a new edition of its *Guide* enumerating parking places for cars in town and country. It appears that there are thirty-one official parking places in central London.

MESSRS W HIFFER AND SONS LTD Cambridge have in the press a book entitled *Notes on Medical Case taking and the Examination of Patients* by Dr G S HAYNES ASSISTANT Physician to Addenbrooke's Hospital. It is intended for the use of students who have passed the second or intermediate examination in anatomy and physiology.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W C 1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring PEPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager British Medical Association House Tavistock Square W.C.1 on receipt of proofs

All communications with reference to ADVERTISEMENTS as well as orders for copies of the JOURNAL should be addressed to the Financial Secretary and Business Manager.

DISCUSSION

WHAT SHOULD BE THE STANDARD OF
PURITY OF MILK?

OPENING PAPERS

I.—R. STANHOUS WILLIAMS, M.B., D.Sc., D.P.H.
(The National Institute for Research in Dairying)

BACTERIOLOGICAL STANDARDS AND A PURE MILK SUPPLY

Bacteriological standards for the cleanliness of milk may be employed in two different ways either as a method of public health control or as a means by which the true essentials of the methods of handling milk and their necessity for the creation of a healthy trade are brought home to the members of the industry. The latter function will in the end, to a great extent eliminate the necessity for the former since the industry will itself, and for its own good, desire that only the best shall be offered to the consumer. I should like, therefore, to be allowed to consider these two aspects of these standards.

Public Health Standards

The bacteriological examination of milk samples as a method of estimating the cleanliness of the milk was only introduced into England in 1917. At that time a sufficient amount of work upon this subject had been carried out in this country to make a tentative standard of 30,000 per cubic centimetre of milk and absence of *B. coli* in two out of three tubes of 1/10 c.c.m. on delivery of the milk to the consumer to be established for certified milk. It is to be noted that this test differs from that which is found in New York in that a count of 30,000 is permitted whereas a count of 10,000 is required in New York. On the other hand a definite standard of freedom from coliform organisms is required in this country, in New York State this is not so. It is probable that the English standard is at least as difficult to maintain as that in New York, and it has the advantage that the inclusion of a *B. coli* test makes it much more possible to control, not only the work in the cowshed but also the efficiency of the methods of washing and steaming all utensils which may be employed in the handling of milk. It is our experience that inefficient methods of washing and steaming of milk utensils are a most potent factor in the increase in numbers of coliform organisms. The use of the two tests is therefore a valuable help to those who are endeavouring to assist the farmer and the dairyman in their work.

As time progressed and with the introduction of the Milk and Dairies Act, 1922 it became possible to lay down further standards for the different grades of milk. An epitome of these is set out in Table I which is slightly modified from a similar table published by the National Clean Milk Society.

This table shows that in addition to the standard for certified milk we now possess standards for Grade A (tuberculin tested) milk, Grade A milk and pasteurized milk when sold under official licence. It will be noted that the coliform test does not apply to pasteurized milk. The reason for this I do not know. The official test for certified milk has now been in use for some years and it may be well therefore to consider whether it can or cannot be maintained. For this purpose I may perhaps be allowed to refer to a paper which was published by Mr. Matthei and myself.¹ It concerns the milk of Mr. Symes, who is working under conditions which do not show any special advantage. The series of samples were taken weekly between April 21st 1921 and June 6th, 1924 a period

TABLE I

Designation	Acids				Coliform Bacillus	Other Conditions
	Tuberculin tested at regular intervals	Inspected at veterinary intervals	Maximum No of bacilli per c.c.			
Certified	Yes	Yes	30 000	—1/10 c.c.		Bottled on the farm the name of farm day of production and word Certified on each bottle cap
Grade A tuberculin tested	Yes	Yes	200 000	—1/100 c.c.		Delivered to consumers in— (a) the bottles or the sealed container as received from the farm (b) suitable containers of not less than two gallons capacity (c) bottles with the name of the dealer by whom the milk was bottled the address of the licensed bottling establishment the day of production and the words Grade A T.T. or Grade A on each bottle cap
Grade A	No	Yes	30 000	—1/100 c.c.		

Pasteurized Milk

Grade A Pasteurized—Grade A milk that after pasteurization as required by the Minister of Health contains not more than 30,000 bacilli per cubic centimetre and no coliform bacillus in 1/10 c.c.m. All other conditions as required for Grade A milk.

Pasteurized—Any milk that after pasteurization as required by the Minister of Health contains not more than 100,000 bacilli per cubic centimetre. No requirement for bottling.

of more than three years. It is to be noted that 1921 owing to the prolonged heat, was a most difficult year for the milk trade. The samples were taken at random from the milk as it was bottled and were at once dispatched by post to the laboratory without placing in cold store. The age of the samples varied from twenty to twenty-four hours at the time of examination.

Up to August 1922 the milk was cooled with water from a town supply. From April 1921, to August 1922 the average temperature of cooling during the months May to September inclusive was 51° F., and from October to April inclusive was 48° F. After this date the temperature of cooling seldom exceeded 50° F., and was usually between 40° and 50° F. Milling was done in the cowshed which is of the type ordinarily found on farms where clean milling is practised. There is no separate milking shed. Table II is an epitome of the bacteriological counts which were obtained.

TABLE II—Bacteriological Counts

Temperature of Samples on Arrival at the Laboratory	Total Number of Samples Examined	Number of Samples containing not more than					No. of Samples containing more than 200 000 Colonies per 1 c.c.
		1 000 Colonies per 1 c.c.	10 000 Colonies per 1 c.c.	30 000 Colonies per 1 c.c.	50 000 Colonies per 1 c.c.	200 000 Colonies per 1 c.c.	
41-53.1	32	22	32	32	32	72	0
51-55	52	44	51	51	51	52	0
56-60	53	42	53	53	53	53	0
61-65	28	15	26	27	27	27	1
66-70	13	8	12	13	13	13	0
71-75	4	1	1	2	2	2	2
Over 75	2	0	0	1*	1	1	1†
Total	184	133	175	179	179	180	4

* 80° F. † 85° F.

This table shows that of the 184 samples which were examined 179 gave counts of 30,000 or less, and that of the five which were above this figure three arrived at the

laboratory at temperatures higher than 70° F. In Table III the results of the coliform test have been epitomized.

TABLE III—Results of the Coliform Test

Temperature of Samples on Arrival at the Laboratory	Total Number of Samples Examined	B. coli Absent in—	B. coli Present in—			
			1 cc	1/10 cc	1/100 cc	1/1000 cc
41-50 F	32	32	—	—	—	—
51-55	52	52	—	—	—	—
56-60	53	51	1	1	—	—
61-65	28	25	2	—	—	—
65-70	13	13	—	—	—	—
71-75	4	2	—	2	—	—
Over 75	2	1	—	—	—	1
Total	194	177	3	3	—	1

The figures in this table are intended to show that coliform organisms were found in the dilutions stated, but not in higher dilutions. Thus three samples showed *B. coli* in 1 cc but not in 1/10 cc and so on. In effect, therefore, four samples showed coliform organisms in 1/10 cc or higher dilutions, and, of these, three arrived at the laboratory at temperatures greater than 70° F.

These results show, first, that it is possible to maintain the Ministry's standard for certified milk, secondly, that success in clean milk production rests not so much on the buildings and equipment as upon the skill of the workers and the unflagging interest of the farmer or milk dealer. It is in the creation of this skill and interest that the Ministry of Agriculture and Fisheries is so deeply interested, and it is to this part of the work that I should like now to be allowed to turn.

Agriculture and Bacteriological Standards for the Cleanliness of Milk

If now we turn to the industry itself it is found that there have been two most potent factors in the recent movement towards a clean milk supply in this country. One of these was the existence of a very small band of people, of whom Mr. Buckley was one, who had of their own initiative created a special market for what is now known as "certified milk." When the war came and the price of milk was controlled, it was realized that these pioneers could not continue to exist if they were only permitted to charge the price current for ordinary milk. The Minister of Food, therefore, acting in conjunction with the Ministries of Health and Agriculture, granted these persons special licences which empowered them to make an extra charge for their better product. Such licences were later extended to any other who might fulfil the necessary conditions. This was one of the great events in the history of the milk industry, since it was an official recognition of the fact that the man who offered a better product was worthy of his reward—the recognition which was sufficient to create a new hope in the hearts of the more inspired members of the industry.

Such licences, however, could only be controlled by some means which would tell the cleanliness of the milk. It was fortunate, therefore, that agricultural educational bodies, working with the Ministries of Health and Agriculture, were already making careful bacteriological studies of the conditions which govern the successful handling of milk. Those studies had their origin in work which was undertaken in 1913, became more specially devoted to the needs of the whole milk trade in 1916, and have continued ever since. In so far as it is possible to foresee even, it is probable that their need will continue for a long time to come. It is work which any man may be glad to do, for it forms the fundamental basis of a vast number of the problems which concern, not only the whole milk trade but also those of condensed and dried milk and of the cheese and butter making industries.

It is not well to weary you with all the details of this work, it is enough to state that it was done with an eye

to efficiency and economy. It was fortunate that it was carried out by those whose primary duty was to help agriculture, for thus it was carried right down into the cowsheds and on to the dairyman's premises by those who were glad to spend the necessary time in assisting the workers who were actually responsible for carrying out the duties involved in the handling of milk. Had it not been for the accumulation of concrete facts based upon careful experimental work it would have been impossible to impart this knowledge efficiently, to explain the causes of error, or to obtain the improved results upon which the whole future of a clean milk supply must depend. That, on the whole, efficiency has been attained is shown by the steadily increasing demand for milk sold under licence. This increasing demand is demonstrated by the constantly increasing number of licences which is shown in Table IV. This table was very kindly prepared for me by Mr. Holt of the Ministry of Health.

TABLE IV

Date	System of Licensing	Producers	Distribution
Dec. 1918	Special Licences	16	4
Mar. 1920	Licence A and Licence B	22	12
Dec. 1920	Grade A (Certified) and Grade A	23	15
Dec. 1921	Do to	33	55
Dec. 1922	Do to	43	121
Dec. 1923	Certified Grade A (tuberculin tested) and Grade A (assured)	14	80 (including 4 bottles depo.) 160 (including 56 depo.)
Dec. 1924	Certified Grade A (tuberculin tested) Grade A (assured)	71 61 52 224	1216 (including 94 bottles depo.) 28 (including 66 depo.)

It is to be noted that although some districts show a greater preponderance of licensed holders than others, they are, none the less, scattered all over the country, and are most common in those districts in which they receive the most active support from those who are responsible for agricultural education and the public health authorities.

The success of this movement depends upon knowledge and constant interest in the work. Knowledge, if it is to be effective, must depend upon careful research, that the true facts may be known, and the results of such research must be brought to those engaged in the industry. It is here that agricultural education authorities, supported by the Ministry of Agriculture, are rendering so great a service to the nation, much of which is perhaps unknown to many of those who are here. Let me therefore try to tell you a little of what is being done.

Ten days ago I was at the Royal Show at Chester. In the tent of the Ministry of Agriculture there was an exhibit showing the methods of handling the milk, and daily lectures and demonstrations were being given. In addition to these the Cheshire School of Agriculture had a tent in the show ground in which the whole process of milking the cow and handling the milk was demonstrated practically three days throughout the show. Such demonstrations are being carried out at endless shows throughout this country and in Wales. The work was begun immediately after the war, and has been continued at an ever increasing number of shows from that date to this. It is astonishing to see the numbers who come to these demonstrations and the interest that is taken in them. But this is not enough. At least two further steps are needed, first, to create the spirit which carries on from day to day, morning and evening, twice a day, seven days a week, and three hundred and sixty-five days a year, in the dark hours of a cold winter's morning just as well as in the bright sunshine of a summer's afternoon, and, secondly, to give for that spirit when it is created.

The first of these objects is being accomplished partly by demonstrations at shows, partly by lectures at fairs,

and dealers' meetings, partly by literature but most of all, perhaps, by the increasing number of clean milk competitions which are being carried out throughout the country. Most of these are conducted upon a common system the conditions of which may be found in the Ministry's *Guide to the Conduct of Clean Milk Competitions*. Two of the main features of these competitions are first, that a very large proportion of marks is given for "methods" the results of which are controlled by the bacteriological examination of samples which are taken in the course of the competition and, secondly, that every effort is made to secure that the competitions shall last for sufficiently long periods to enable those who are competing to develop a new habit of mind. Table V shows how greatly these have increased in number during the last few years. It is to the honour of Essex that the first competition of this character was held in that county in 1920 on the initiative of Howard Dimes and of Captain Skelton, a producer of certified milk, working in collaboration with the Agricultural College at Chelmsford.

TABLE V.—Clean Milk Competitions

Year	No. of Counties competing
1920	1
1921	2
1922	3
1923	3
1924	19
1925	33

From these competitions much is learnt. Here, for example, is an illustration taken from the competition which was held in the counties of Nottingham, Leicester, and Derby during the period October 1st, 1924, to March 31st, 1925. In Table VI are set out the results of the bacteriological examinations of the first and eighth samples of milk taken during the competition.

TABLE VI

Bacterial Count	No. of Competitors		B. coli Present in—	No. of Competitors	
	First Sample	Eighth Sample		First Sample	Eighth Sample
Millions	2	0	1/1000 c.c.	5	2
1-27 million	1	0	1/100 c.c.	5	2
1 million	3	0	1/10 c.c.	0	1
250 000-500 000	0	0	1 c.c.	2	1
100 000-250 000	1	1	Ab sent from 1 c.c.	3	9
50 000-100 000	0	0	—	—	—
20 000-50 000	3	1	—	—	—
10 000-20 000	1	1	—	—	—
5 000-10 000	1	0	—	—	—
2 000-5 000	0	4	—	—	—
Less than 2 000	3	8	—	—	—

If this table be examined it is found that in the first series of samples six showed counts of half a million or more, this number was reduced to none in the eighth series. On the other hand, in the first series only three samples showed counts of 5 000 or less, this number was increased to 12 in the eighth series.

The attempts to eliminate *B. coli* were not quite so successful, but nevertheless there was a definite improvement, since the numbers of samples showing this organism in 1/1000 c.c. were reduced from 5 to 2, and the numbers of those showing *B. coli* in 1/100 c.c. were also reduced from 5 to 2. On the other hand, the number of samples which showed complete absence of *B. coli* in 1 c.c. was increased from 3 to 9.

The relationship which exists between the bacteriological content and the keeping qualities of the milk is brought out in Table VII, in which the keeping qualities of these same samples are set forth.

TABLE VII.—Keeping Qualities

Days of Sweetness	First Series of Samples	Eighth Series of Samples	Days of Sweetness	First Series of Samples	Eighth Series of Samples
4	0	0	22	2	6
3	0	0	3	0	0
1	0	0	3½	1	2
1½	0	0	7½	0	0
1¼	2	0	3½	2	1
1½	1	1	4	0	1
2	2	0			
2½	3	4			
2¼	2	0			
				15	15

The effects of the improvements in the bacteriological content upon the keeping qualities of the milk are clearly demonstrated, since the table shows that three of the first series of samples failed to keep sweet for more than one and three quarters days, whereas in the eighth series this number was reduced to one. Again, in the first series of samples ten kept sweet for more than two days in the eighth series this number was increased to fourteen. When these results are further examined it is found that the average duration of sweetness of the first series of samples amounted to 58.8 hours, the average duration of sweetness of the eighth series was 66.4 hours. The improvement in the methods of handling the milk had increased the average duration of sweetness of the samples by no less than seven and a half hours. If one remembers the extreme importance of the duration of sweetness of the milk in promoting the sale of milk this result represents a most important advance.

These tables show the importance of the study of bacteriological standards if the conduct of the milk trade is to be successful, but I should like to be allowed to go one stage further and give you an illustration of an observation that has been made which will, I believe, prove to be of great importance to the industry and will demonstrate the value of preserving the coliform test. Work of this character is being carried out by Miss Hickson at the National Institute for Research in Dairying but I will content myself with a simple illustration taken from a recent competition which Mr. Mercer of the Cheshire Agricultural College has been conducting in that county. In the course of this competition 87 samples showed counts which lay between 1 000 and 5 000. Coliform organisms were not found in 1 c.c. in 57 samples, they were found in 1 c.c. or in higher dilutions in 30 samples. Table VIII shows the total duration of sweetness and its average duration in each of these groups.

TABLE VIII.—Bacteriological Counts 1 000 to 5 000

Coli Absent from 1 c.c.			Coli Present in 1 c.c. or Less		
No. of Samples	Keeping Qualities in Days	Average	No. of Samples	Keeping Qualities in Days	Average
57	202½	3.5	30	9.5	3.18

These figures demonstrate that the average duration of sweetness of the samples which did not show the presence of coliform organisms was 3.5 days. On the other hand, the duration of sweetness of those which did show their presence was 3.18 days, a difference of 0.32 day, or more than seven hours, a very appreciable gain.

The great value of bacteriological standards to the industry itself is thus again made clear for it is by these, and by these alone, in the present state of our knowledge, that it is possible to rescue the work from the fog of talk and opinions. So far you have seen that the imagination is being stirred, and is then being encouraged to practise. It remains to see what steps are being taken to give that constant help which is necessary to prevent falling off and thus discredit to our industry. That this may be accomplished the Ministry of Agriculture is offering encouragement to agricultural colleges and county educational authorities to make special appointments for the conduct of this work. Such appointments have been made

in various counties, and in addition it runs in agricultural colleges and university centres—is, for example, Bristol, Bangor, Leeds, Cambridge, and the South-Eastern Agricultural College at Wye. There may be others which I have forgotten, but the list is sufficiently long to demonstrate to you the widespread interest which agriculture is taking in the promotion of this kind of knowledge. The men who undertake this kind of work and their colleagues are prepared, not only to carry out bacteriological tests in the laboratory, but also to go down into the cowsheds and on to the dairymen's premises and study the conditions under which the work is done. By these means they will make their work effective and prevent mistakes.

If I have succeeded in demonstrating to you the magnitude of the efforts which agriculture is making in the promotion of a clean milk supply, then this paper has fulfilled its function. It only remains for me to say, what I have often said before, that the members of the staff of the National Institute for Research in Dairying will give all the help they can, and may I add how proud I am to think that bacteriology is being justified of her children?

II—WILLIAM G. SAVAGE, B.Sc., M.D. LOND., D.P.H., County Medical Officer of Health, Somerset

I THINK the word "purity" should be interpreted in this connexion with a fairly wide meaning, and include within its scope abstraction of contents, such as fat, since this often implies the replacement of that constituent by water, which I regard as a lowering of the standard of purity. The public health administrator makes four demands as regards the milk supply:

- 1 That it shall not serve as a vehicle for the transmission of infectious or other diseases
- 2 That its nutritive qualities shall not be impaired
- 3 That nothing shall be added to it of a chemical nature which may prejudice the consumer
- 4 That its price shall be as low as practicable, after the above three postulates have been satisfied, so that this fluid shall be readily available to the community

All four demands merit careful consideration.

(1)

That milk has served in the past, and continues to serve at the present time, as a vehicle for the spread of infectious diseases is a well attested fact. The diseases so spread include tuberculosis, diphtheria, typhoid fever, paratyphoid fever, dysentery, scarlet fever, Malta fever, infective sore throats, epidemic diarrhoea, cholera, and food poisoning. Others less common are foot-and-mouth disease and anthrax. The pathogenic bacilli gain access from two main sources. One is the cow, who may herself suffer from tuberculosis, streptococcal mastitis infective to man, or from infection with one of the food-poisoning bacilli or *Micrococcus melitensis*, or, less commonly, may become infected on the teats with the organisms of diphtheria and perhaps scarlet fever. More commonly the infection is conveyed by human agency, and extensive multiplication of the specific organism takes place in the milk, a very favourable culture medium. Such specific infection may be direct into the milk from the infective person or indirect from imperfectly cleansed vessel or impure water. The recorded outbreaks of acute infectious disease spread through milk run into very many hundreds while the extensive mortality and amount of disease due to the bovine tubercle bacillus is only too well known.

Knowing these facts the public health administrator demands that the production, handling and distribution of milk shall be treated as something which requires special care and attention. He asks that steps shall be taken to ascertain that the milk and butter production shall be free from disease which will render them likely

to shed infective bacilli into the milk. It is impracticable, considering the extent to which cows are infected with tuberculosis, to require freedom from that disease, but it is legitimate and reasonable to demand that steps be taken to reduce to a minimum the liability to excrete living tubercle bacilli into the milk pail.

He asks that all who come into contact with the milk at any stage shall be the object of special supervision, and that their state of health be subject to control and investigation. It is also a reasonable requirement that the processes of milking and subsequent milk handling shall be carried out with care and cleanliness so as to admit as few extraneous bacilli as possible. Our knowledge of the prejudicial nature of such bacilli is limited, and we are not in a position to conclude that the bacilli in cow dung, or from other adventitious sources, are harmless, particularly to the young or the invalid. In fact we do know that many tubercle bacilli even from cows showing no evidence of open tuberculosis are carried into the milk while animal streptococci of unascertained virulence are added in this way.

To provide an adequate system of milk control which on the one hand will be effective and on the other will not be unduly restrictive and vexatious in its working is admittedly a difficult task. One solution is to abandon control at the source and to trust to a system of universal pasteurization before distribution to ensure safety. This is a short cut which prevents considerable objections. Some authorities advocate an extension of the principle of graded milks to include all types—good and bad. This implies a regular system of bacteriological standards. Fixed bacteriological standards of milk, non-compliance with which is a punishable offence, have been studied and put into operation in the United States of America. They have many objections, one being that they do not necessarily pick out the worst offenders and another that they do not give any guarantee of freedom either from the tubercle bacillus or from the risk of spreading acute infectious diseases. More practical methods are the extensive use of bacteriology as a sorting agent to pick out milk producers whose methods of handling milk are below a reasonable standard and the provision of a reliable system of supervision and inspection. These must include both the cows and those who handle the milk in any stage. Notification of all cases of illness of the staff to the medical officer of health followed by systematic supervision and examination is a necessary procedure. These different methods are only touched upon here since they will no doubt be discussed in detail in the afternoon session.

Lastly in this connexion the public health administrator demands that any processes of pasteurization or other process advocated to remove these proved dangers of an infective milk supply should be carefully considered as regards any possible prejudicial effect on the qualities of the milk, while such processes should not be allowed to be haphazard but should if permitted at all, be exactly specified, frequently supervised, and effectively controlled.

(2)

The medical officer of health regards milk as the most valuable food we possess and is jealous that its nutritive qualities should not be impaired. Its value as a food is based upon its valuable fat, carbohydrate, and protein constituents, its high content in vitamins, and its mineral constituents.

As regards its ordinary food constituents every medical officer of health who has studied the subject and been brought into touch with the working of the Food and Drugs Acts is profoundly dissatisfied with the present legal position. The more recent legal decisions allow any fluid obtained from the cow to be called "milk," however deficient in food constituents, provided there is no evidence that direct adulteration has resulted. They make it legal for the rich strippings to be wilfully skimmed and the fat-deficient remainder to be sold as milk, thus elevating the calf as of greater importance than the human infant. They allow what amounts to legal adulteration to take place by failing to penalize a milk producer who neglects to feed his cows properly and thus inevitably to produce poor quality milk.

Faced with the present legal position one remedy frequently advocated is to define milk as something which must have a definite chemical constitution, that usually accepted being the present presumptive standards of 3 per cent fat and 8.5 per cent solids not-fat. Such a remedy would press unfairly upon the smaller purveyors and producers. The big milk vendors with skilled staffs and working with a large bulk of milk could reduce to the legal limits to a nicety, while the small man would be unable to hit the happy mean between a profitable abstraction and an excessive but illegal removal.

We now know a great deal as to the composition of milk from different sources and at different seasons of the year. Seasonal variations are considerable, and it should be possible to have two standards to conform with these variations. One, in my opinion, should be above the present standard, the other the existing one. It is necessary to protect the milk producer and vendor, and my own solution of this difficulty remains what I stated in 1912.¹ This is to give the owner of the milk prompt notice (without prejudice) of the fact that his milk is below standard, and to provide facilities for examination of the mixed milk of the herd to be sampled before any question of prosecution is entertained. If the mixed milk is also found below the standard no prosecution would result, and the local authority might even pay the cost of this second examination. If the purveyor of the deficient milk failed to avail himself of this means of protection he should not be permitted to use the plea that it was from impoverished cows, and the analyst's certificate would be final. It would not operate for large bulk milk supplies, but genuine milk in bulk is not below legal standards. It should be supplemented with legal powers requiring milk producers to improve the quality of the milk given by cows when proved to be deficient.

As regards vitamin content, it has now been demonstrated that this fluctuates with conditions which are controllable, and it is reasonable to ask that the conditions of feeding and storage shall be such as will result in a reasonably high vitamin content.

The salts content does not directly raise questions of standards of purity. Indirectly both this and the vitamin content are influenced by any heat processes to which the milk may be subjected, and this aspect has already been mentioned. If milk is sold after heat treatment, that fact should be declared.

(3)

The subject of chemical additions to milk need not be more than mentioned, since it is now legally recognized that the addition of preservatives and colouring matter to milk is not permissible.

(4)

The price at which milk can be sold at a profit is of decided interest to the medical officer of health. While not strictly germane to my discussion on standards of purity for milk, it cannot in practice be left out of consideration, since it does affect in a very practical manner the standards to be accepted. The opponents of any system of efficient milk control invariably raise the bogey of enhanced cost, and vociferate that any efficient control will so increase the cost of milk production and distribution that it will become more esbale to the poor, and the last state will be worse than the first.

If we free ourselves from the demands of the extremists there is no real reason why the measures outlined above for the safeguarding of the milk supply should send up the cost of production appreciably. There are a number of ways, many now neglected, by which the cost of milk production can be reduced. The Committee on the Production and Distribution of Milk pointed out eight of them. If it is so important to keep down the cost of milk, why allow these to be neglected and fasten attention on the one factor which is of public health importance? Reasonably interpreted, an enormous advance in the safety of our milk supply can be attained with little or no increase in the cost of milk production. Undoubtedly the cost of supervision will be increased. This however, should not

fall upon the milk trade, but be part of the general public health expenses of the country, and therefore would not affect the price of milk.

In my section of the discussion I have avoided any consideration of bacteriological standards, as this point of view is in the crumble hands of Dr Stenhouse Williams. I have attempted to look at the subject from the aspect of the public health administrator and official. I would suggest that what I have advocated on his behalf is fully justified by the scientific data available. As regards the best methods of obtaining these standards of purity, there will no doubt be legitimate grounds of divergence. To solve the difficulties of the milk problem and obtain a solution which will be fair to the agricultural interests, to the milk trader, and to the consumer will require the most careful co-operation of the administrator, the bacteriologist, and the practising physician, as well as of the trade itself. This side of the problem will be discussed this afternoon, and is beyond the scope of the present discussion.

III.—ERIC PRITCHARD, M.D., Medical Director, Infants Hospital, London

THE POINT OF VIEW OF THE CLINICIAN

My contribution to this discussion will be confined to the consideration of the standard of purity required in milk intended for consumption by infants and children, for I take it as granted that milk which is good enough and safe enough for them is good enough and safe enough for the rest of the community.

In considering standards of purity we should be careful to distinguish between those which are concerned with the exigencies of nutrition and health and those which are demanded by our aesthetic tastes. A milk which is perfectly safe, as far as its consumption by infants is concerned from the point of view of its bacterial content and nutritive value, may be repugnant to the refined tastes of a fastidious adult, for the reason that in the process of production or distribution it has been handled in a manner which offends against his notions of decency, propriety, and cleanliness. For instance, I think few of us would care to drink a glass of milk, even though absolutely sterile and therefore clean in a bacteriological sense, which we knew to have been drawn from the udder of a cow by a milker who constantly spat upon his hands. The presence of a small quantity of sterilized faeces or urine in milk would not prejudice its nutritive value nor render it harmful to the health of the most delicate infant, but a knowledge that it had been so contaminated would certainly interfere with our enjoyment of it as a food or as a beverage.

I well remember some twenty years ago how I was completely prejudiced against the drinking of milk after I had witnessed the process of cleaning some 500 gallons of milk by its passage through a centrifugal machine and the removal of a pint or two of the most filthy-looking sludge which contained cow's hairs, faecal matter, and slimy mucus. The milk from which this loathsome foreign matter had been removed was, after pasteurization or scalding, a perfectly safe and nutritious food for infants and children but hardly one which would commend itself to the refined tastes of an epicure.

Milk is such a valuable food both for infants and children and for the community as a whole, not only from the point of view of the nutritive qualities of its energy-containing elements especially the fats and proteins, but also in respect to its mineral extractive, and vitamin content that any attempt by legislative or other means to attain Utopian ideals of cleanliness irrespective of cost would be little less than a national calamity. Although it is possible with sufficient knowledge and adequate resources to compound a mixed diet that it contains all the thirty or forty individual constituents of milk, nevertheless I now from experience that the moment the child passes from the milk age to solid food age it is deprived of a number of necessary elements essential for nutrition.

The drinking of milk is indeed a most reliable guarantee

against a number of pathological conditions to which French writers have applied the term, "enfance frêle" or "hypocaenece." In his excellent book on vitamins Ragnar Berg constantly refers to the prevalence among children and adults of minor degrees of ill health, due to deprivation of the very elements, mineral and organic, which are so richly represented in milk, conditions for which he has suggested the comprehensive name of "larval deficiency diseases."

The experimental feeding of school children on additional rations of milk has been conclusively proved by W. M. Frazer and others to be immediately followed by a marked improvement, not only in their general physical condition but also in the degree of their mental alertness. In view of these indisputable facts, I submit that we should be careful not to impose conditions on the milk industry, which, with the object of securing high standards of bacterial purity, may at the same time raise the cost of production to the prejudice of its more extended consumption.

Although milk is undoubtedly the most valuable of all food commodities it is at the same time without question the most dangerous vehicle for the conveyance of infectious disease, and the whole history of the clean milk movement both in this country and in the United States of America is to prove that the commercial production of a raw milk which is safe from this point of view is an impracticable proposition. In order that milk may be made safe for human consumption it must be treated in some way which renders it free from pathogenic organisms, and so far no means other than exposure to degrees of heat sufficient to kill such disease provoking agents has been devised by the wit of man. At the National Milk Conference on Pasteurization held in London in 1923 Dr. S. G. Moore, M.O.H. Huddersfield, summed up the whole situation when he said: "Pasteurization has been said to be a confession of failure. I do not call it a confession of failure, but a recognition of inexorable facts." And in spite of all arguments to the contrary, and in spite of what has been said before and will probably be said again during the course of this discussion I thoroughly agree with him.

To my mind it does not come within the range of practical politics to consider whether milk should be rendered safe by exposure to heat or whether it should not, but rather how when and where the heat should be applied—how clean it should be and what degree of bacterial contamination should be allowed before pasteurization or other form of sterilization.

Since it is universally admitted that milk may become contaminated by the cow, the producer, the distributor, or the consumer it does not appear to me to be logical to look for complete safety from milk infections unless the milk is rendered sterile of pathogenic organisms immediately before consumption, and to attain this end I do not see any alternative to some method of home pasteurization or scalding. If we are prepared to dispense with absolute safety and acquiesce in relative safety, the only solution to the problem is the commercial pasteurization of the whole milk supply.

I do not wish to insult the intelligence of this meeting by seriously raising the question as to whether the nutritive qualities of milk are dangerously prejudiced by the process of pasteurization. This old bogey has, I hope, been finally disposed of by the teaching of our newer knowledge of nutrition. Out of the thirty or forty essential constituents of milk it is possible that one or two may be slightly impaired in biological value by the application of heat, but even with this admission the balance of advantage is so enormously on the side of safety, and any minor defect so easily compensated for in the case of children, and so utterly unimportant in the case of adults existing on a mixed diet, that objections to pasteurization on this count need not be considered seriously. I would like, however, to point out to the few who still hold contrary views and persist in the unachismism of the raw milk doctrine, that the changes to which raw milk are submitted in the stomach are of far more revolutionary and drastic character than any to which it is submitted by the application of heat outside the body. If, then, "in recog-

nition of inexorable facts," to use Dr. Moore's wording, we are driven to some form of pasteurization of milk to render it safe for consumption, how is the method to be applied, and how clean is the milk to be before treatment?

As far as the specific infectious most commonly conveyed by milk—namely, those of bovine tuberculosis, human tuberculosis, typhoid fever, paratyphoid fever, diphtheria, and septic conditions—are concerned, we learn from the report recently issued by the United States Public Health Service (Bulletin No. 147, February, 1925) that milk can be rendered sterile with a considerable margin of safety by improved methods of commercial pasteurization in which it is held for thirty minutes at a temperature of 145° F. The experimental researches on which this report is based were of a very searching nature. For instance, 4,000 quarts of milk containing 10,000,000 tubercle bacilli per cubic centimetre were pasteurized in bulk and rendered sterile, and similarly 4,000 quarts of milk containing 30,000,000 typhoid bacilli were treated and rendered sterile. Incidentally, I may mention that one of the results of these very elaborate investigations has been to show that the lethal temperature for certain pathogenic organisms is lower than is usually believed—for instance, in milk pasteurized in bulk, the lethal temperature was as follows:

For the bovine tubercle bacillus	138° F. in 30 minutes
For the typhoid bacillus	132° F. in 30 minutes
For the diphtheria bacillus	129° F. momentarily
For haemolytic streptococci	125° F. momentarily

From this report and the investigations on which it was based—a report which was prepared under the direction of Dr. L. Clinck North with a staff of the most experienced scientific and practical milk experts in the United States—it is abundantly clear that the commercial pasteurization of the milk supply is a practical proposition under adequate supervision, and it goes without saying the same is true of the home treatment of milk, by boiling or scalding provided that the public can be induced to see the necessity for such precautions.

If, then, milk can be rendered safe, as far as the specific infections are concerned for immediate consumption by the processes of commercial pasteurization or by scalding in the home, are there any dangers to be interpreted from toxic substances resulting from the activity and development of germs in milk prior to the time of sterilization, or from the survival of varieties of spore forming bacteria not specifically pathogenic and not destroyed by the degrees of heat to which the milk has been submitted? This, indeed, is a very serious question, and one that cannot be answered definitely in the light of present knowledge.

As regards the presence of toxic substances in milk, in Bulletin No. 41 of the Public Health and Marine Hospital Service of the United States (1908) which deals with milk and its relation to the public health, there is a good summary of the then existing knowledge on the subject, and a full bibliography by Joseph H. Kastle, and as far as I am aware our knowledge has not been supplemented since. From this it would appear that stale milk can contain toxic substances of bacterial origin (tyrotoxicon) capable of producing symptoms (galactotoxism). Several epidemics and sporadic cases due to this cause are reported. I have myself seen two cases of severe vomiting in infants occurring immediately after the consumption of stale sterilized milk, kept in bottles, in both cases there was a strong smell of sulphuretted hydrogen. The results followed so immediately on consumption that bacterial infection could be definitely excluded. Whether or no the repeated consumption of slightly toxic milk can by its cumulative effect inflict damage on the human organism is a moot point. But common experience goes to prove that no such injurious results follow the use of sterilized or pasteurized milk when such milks have been used for infant feeding on a large scale. The possibility of such accidents must not, however, be ignored if commercially pasteurized milk is allowed to grow stale even though such milk is again pasteurized immediately before consumption.

The chief objection to the indiscriminate use of commercially pasteurized milk for the feeding of children is that this process has a selective lethal influence on the

bacterial flora. Although when properly conducted, it ensures the certain death of all pathogenic organisms and a large proportion of the non-pathogenic varieties, including the lactic fermenting group, it permits of the survival of a considerable contingent of resistant, spore-forming and putrefactive bacteria, which thus have an opportunity of development subsequent to pasteurization both inside and outside the body, unchecked by the restraining influence of their fellow lactic acid bacteria. Unfortunately we know very little about the significance of a mixed bacterial flora in the alimentary tract, we hardly know what is normal and what is not, but, speaking solely from my own experience, I can state very definitely that the stools of infants fed on milk which has been deliberately soured by twelve hours' incubation with a known dosage of the lactic acid bacillus are very different from the stools of infants fed on pasteurized milk. The latter class of stools is invariably alkaline in reaction, more or less offensive, and quite different in character from those of infants who have been breast-fed. At the Infants Hospital, although our milk supply is beyond reproach, we now invariably sour the milk which is supplied to premature or young babies who are not breast-fed, the stools are usually acid in reaction, free from the odour of decomposition, and far more like the natural stools of breast-feeding, and the results generally far more favourable than before we adopted this method.

The bacterial count of such milk after treatment usually lies between 60 and 600 million lactic acid bacilli per cubic centimetre almost in pure culture, a count which would very justly condemn any milk offered for public sale. I regard it as very probable that the susceptibility to intestinal infection of infants who have been fed for any length of time on dirty milk with a high bacterial count is due to the constant reinforcement of the digestive tract with a mixed and dominant strain of putrefactive organisms. For this reason alone I regard standards of purity for the public milk supply as absolutely essential for the safety of infants and children, and since a differential count is at present out of the question, the only practical standard that we can adopt is one based on the total number of bacteria present in milk irrespective of the particular species.

For my part I am well satisfied with the standards required under the terms of the Milk (Special Designation) Order (1923), provided that the pasteurization of all milk not attaining the Grade A standard is made obligatory.

A relatively safe milk for the whole community, rich and poor, purchasable at a relatively cheap price, should be our great consideration, by some system of controlled inspection, and in the case of all milk not coming up to the highest standard, by controlled pasteurization. The quality of the milk should be guaranteed, and high grades, for which a correspondingly high price may reasonably be expected, should only be supplied in sealed bottles, with the time, date, and place of sealing clearly designated on the caps. By such means the health of our child population would be reasonably safeguarded, and ample provision made according to their respective means and fancies for the more fastidious tastes of those who can afford milk of a better quality.

GENERAL DISCUSSION

Mr WILFRID BUCKLEY (London) demurred to two statements in Dr Savage's address: first that the percentage of butter-fat in milk could be altered by feeding, and, secondly, that conditions of feeding could assure a high vitamin content. Mr Buckley thought that the alteration of the percentage of butter-fats by feeding was not borne out by experience, that a definite standard of butter-fat could not be set up, and that often the 3 per cent standard could not be maintained. He would like to know how Dr Savage proposed to use food to produce a high vitamin content. When grass is not available, a diet of oats would not produce sufficient albuminoids; consequently the farmer had to rely on cake. Dr Savage's proposition was really impracticable.

Mr J T QUINTON (Liverpool) supported the view that the milk supply needed special legislation, the danger of using preservatives in milk might be dismissed from their

minds. In some 24,000 samples examined, only 10 contained preservatives, and in those the quantity was very small. For a low bacterial count the sterilization of milk vessels was essential. They needed to encourage the production of good milk, and at the same time to pay for the quality produced. Mr Quinton suggested that in dealing with large quantities of milk the price should be fixed in accordance with the percentage of fats.

Mr BEN DAVIES (United Dairies) said that Dr Savage had left out one of the most serious causes of contamination in milk—a cause which killed many babies—contamination in the home. This should be recognized when legislation was promoted. In support of this view he quoted Dr Robert Hutchison, Sir John Robertson, and Sir George Newman, who was quoting from Sir Arthur Newsholme. Mr Davies said that he was the first to introduce certified milk, but that he was a convinced pasteurizer. The suggestion that milk might be toned down in large cities was an idea which had no existence in fact—at all events in regarded London. The records of metropolitan boroughs showed that the analyses of all the samples of milk taken during the year by their inspectors give an average fat content of from 20 to 25 per cent above the Government standard. As regards the healthfulness of the milk supply, Sir Frederick Anderson had stated that the milk supply of the City of London was now purer than ever before in its history. It was sometimes suggested that because of his reliance on the protective virtues of pasteurization the milk distributor was less careful than he might be of the original quality of his milk; this again was at variance with the actual facts. The speaker had taken out the average plate counts for four years of the very large quantities of milk with which he had to deal, and found that its bacteriological quality had enormously and continuously improved. The relative number of bacteria in the milk as received from the producer was as follows: 1922, 50; 1923, 28; 1924, 22; 1925, 16. Such results were the reward of an enormous amount of painstaking and costly effort, and showed that the London milk supply was being developed on lines which would place it beyond criticism.

Mr J C COLLYER (Swindon) thought that the production of clean milk did not pay the small producer; the increased cost over ordinary milk was absorbed by the distributor. Clean milk required clean production, and it was impossible to obtain milk which was dirty. Some of the difficulties of clean production were due to the disparity of the wages of the farm labourer and of the distributor's employees. Mr Coleman stated, amidst some dissent, that while the former received 30s a week, the latter earned £4 to £5 and in many cases a bonus on sales.

Mr P B TUSTIN (United Dairies) said that an interesting experiment had been conducted recently by the Medical Research Council in an institution for boys between the ages of 6 and 10 years. One section of these boys had been given one pint a day each of pasteurized milk and it had been proved that pasteurization did no harm to the nutritive value of milk. Mr Tustin thought that people suffered rather from too little milk than from had milk. Real progress in improving the milk supply could only be achieved by getting the producer, the distributor, and the controller together to find out where the difficulties of each might lie. In Chicago, where this had been done, there had been no case of outbreak of infectious disease from milk for the last ten years. Dr Savage had enumerated a long list of fearful diseases which might be caused by milk. Would he give a list of the outbreaks of these diseases recently which could be traced to milk? Mr Tustin wished to know if oilcake containing cod-liver oil was quite without vitamins; the authorities should tell the producer more in this matter. Bacterial content should be estimated by a series of counts and not by an isolated count. The bacterial count was valuable in suggesting faults in the supply. Pasteurization should not be used to disguise dirty milk. Mr Tustin again urged that reading out lists of all the horrible things that might happen was of no value compared with getting together those engaged in the milk supply for the purpose of discussing their difficulties.

Mr S R WHITTY (British Dairy Farmers' Association) was quite convinced that there were a thousand ills arising from the deficient use of milk is compared with every one due to bad milk. The English people were undoubtedly consuming a grossly inadequate amount of milk per head, on the other hand, doctors who ought to have been emphasizing the advice "Drink more milk," had in the past said "Drink less milk." During recent years there had been an enormous advance in the care devoted to the production of milk, milk competitions were going to help in the improvement. Mr Whitty implored doctors to help in increasing the production and consumption of milk, by doing this they would, moreover be rendering a valuable assistance in the most important work of improving agriculture generally.

Dr H SCURFIELD (Colleston) asked for information about the attitude of the big distributors towards this problem. Were they offering any inducements to their customers to take clean milk, and were they co-operating in any definite way with Dr Savage in his endeavor to bring about improvements in the milk supply in Somerset?

Mr R BOUTFLOUR (Agricultural Office, Wilts) mentioned the difficulty experienced by producers in keeping up the standard—especially of butter-fats—in milk at all times of the year. He thought that medical officers of health should be prepared to sympathize with the difficulties of producers, and should make a practice of observing certain farms and of learning the difficulties that had to be contended with.

Dr STEPHENSON WILLIAMS, replying to Mr Quanten stated that the value of the bacteriological tests for the cleanliness of milk depended upon a series in each case and not upon individual samples. When used in this way the test would be found to be of very great assistance in controlling the supply of milk.

Dr SAVAGE said that he wished to impress upon his critics that in his address he was simply putting before them the views of the administration. He was strongly in favour of the increased production of milk, but medical men were able to perceive the dangers in milk, while at the same time anxious to increase its consumption. In reply to Mr Buckley Dr Savage said that he was under the impression that it was possible by feeding to increase the quantity of fluid in the milk without increasing the fats, with the result that the percentage of fats was lowered. They were now learning much about vitamins and Dr Savage thought that in the future it would be possible to increase the vitamin content by methods of feeding. He could inform Mr Fustin that many outbreaks of infectious disease could be traced to milk. To Dr Scurfield's question the reply of the distributors would be, "We pasteurize our milk, why should we bother about giving higher prices to clean producers?" Dr Savage did not think the consumer was a great cause of the contamination of milk, probably he did no more than cause germs, previously in the milk, to multiply.

Dr ERIC PRITCHARD, replying to Mr Coleman's statement that it was impossible to clean milk which was dirty, called attention to the fact that in a milk supply dirty milk was milk containing excess of bacteria. Pasteurization destroyed bacteria, and therefore rendered dirty milk clean. He had found it impossible to get any definite information as to the effect of the toxins of bacteria if ingested with milk. The toxins of pathogenic organisms did not produce any effect, and the non-pathogenic organisms had not been proved guilty.

Cinematograph Demonstration

After the conclusion of this discussion two cinematograph films were shown to illustrate several of the points which had been raised. One film displayed the various steps in the production of certified milk on an English farm, and the other dealt with the precautions observed in the course of handling and distributing milk in New York City.

DISCUSSION BY WHAT MEANS CAN PURER MILK BE OBTAINED AND AT WHAT COST?

OPENING PAPERS

I—WILLIAM BUCKLEY, C.B.I.,
National Clean Milk Society

THE POINT OF VIEW OF THE PRODUCER

In considering the requirements for a standard of quality for milk there are two separate aspects that must be dealt with: the chemical composition and the hygienic quality. The first, the chemical composition, embraces broadly three factors—namely, butter fat, solids not fat, and vitamins. Milk reaches the consumer, so far as chemical composition is concerned, as it leaves the cow (except for the changes brought about by the action of bacteria) unless it has been tampered with, therefore the problem of a standard is comparatively simple, so far as it concerns the chemical composition. Such variations in the chemical composition as do occur are largely beyond our power to control.

The percentage of butter fat in cow's milk varies from day to day in herds and, to a greater extent, in individual cows. It is common knowledge that the milk of Channel Islands breeds is richer in this respect than that of short horns or of Holsteins, and that the butter fat content of individual samples can be varied by the periods that are allowed to elapse between hours of milking. It is also well known that as the cow's period of lactation advances the percentage of butter fat increases. Variation in the kind or quantity of food that the cow receives, so long as she receives sufficient to maintain her health, does not appear to affect the proportion of butter-fat she yields, although the chemical composition of the fat may be altered.

The percentage of solids not-fat varies comparatively little, and it appears that on the occasions when the butter-fat content in the milk of the individual cow increases or decreases below the normal or average, there is a tendency for the solids not fat to vary in the opposite way—to increase when the fat diminishes and to decrease when it increases. The presumptive standards of 3 per cent for butter-fat and 8.5 per cent for solids not-fat are firm standards and can usually be maintained, although the morning milk of individual cows, and less frequently of herds, falls below these figures on many occasions particularly in regard to butter fat. The evening milk usually falls below these standards. The means to attain these standards on all occasions is beyond our present knowledge. The vitamins in milk do depend upon the food consumed by the cattle; this such foods as grass and clover provide a maximum of vitamins.

The hygienic quality of milk is a much more difficult matter to regulate, although, unlike the question of chemical composition, it is one which can be controlled to a greater or to a lesser extent. It depends upon the care exercised by those who produce the milk and by those who handle it from the moment it leaves the cow until it is consumed.

When one considers the standard that should be required for milk of satisfactory quality, one should bear in mind always that milk, as it leaves a healthy cow, is a perfect product, no matter what may be the surroundings where it is produced. Nothing can be done subsequently to improve it. The question that arises is as to the amount of damage it may sustain before it may be deemed to have fallen below a reasonable and satisfactory standard. The aim of all producers and distributors of milk must be to get milk to the consumer in a condition as near as possible to that in which it should leave a healthy cow.

The first point to be considered is the health of the cattle that produce the milk. The cows should be in perfect health, and in particular must suffer from no disease that can be conveyed to man. The most dangerous disease that may be conveyed by milk from a diseased cow to the consumer is tuberculosis. Tuberculous milk may come from cattle with diseased udders, or from cattle that have tuberculous lesions in some other part of the body from which tubercle bacilli are liberated into the blood stream, or the

milk may become infected by manure containing tubercle bacilli that, through carelessness, is allowed to get into the milking-pail. The most practical method of ensuring that no milk from a herd contains tubercle bacilli is by means of a careful and regular application of the tuberculin test to all the cattle, all lactating or doubtful animals being discarded immediately. In practice it is found that to maintain a herd entirely free from tuberculous animals the most (economical or perhaps the only) method is to breed all animals, or at least to make purchases only from herds that are regularly tested and which are found to contain a minimum of reactors.

The maintenance of a herd in regard to which the health of the animals is left to chance costs considerably less than the maintenance of a herd that is known to be healthy. Milk from the former cannot be regarded as satisfactory. Milk from a herd not known to be healthy may cost to produce in the neighbourhood of twopenny a gallon less than that from a herd that is free from tuberculous animals as shown by the tuberculin test.

Apart from the health of the herd the only other consideration is that of cleanliness—cleanliness of the cows, of the milkers, and of all utensils with which milk comes into contact. A satisfactory milk supply requires extreme cleanliness throughout. The milkers must be clean in person and in method. If slovenly methods are employed such as milking with dirty or wet hands, if the cow's udders and flanks are not cleaned, washed, and wiped before milking, if the milk is left in open vessels in the cowshed instead of being removed immediately to the milk room, the milk is damaged, it is worth less, and the producer should be paid less for it. Where cows are properly washed and groomed before each milking it takes about three minutes to prepare a cow properly before she is milked. Assuming that a cow gives two gallons of milk daily, or one gallon each time that she is milked, and that a milker is paid at the rate of 7½ p. an hour, the producer who omits this necessary work saves three eighths of a penny a gallon, and should be paid at least that much less for his product.

In order to ensure that the utensils with which milk comes into contact are scrupulously clean, they must be sterilized by steam. This can be done by any farmer for there are various kinds of sterilizing apparatus on the market suitable for large or for small herds. The omission of this necessary requirement saves a little in expense, perhaps a further farthing a gallon.

It is advisable that milk should be cooled as soon as possible. I have not dealt with this aspect because it is the common practice to cool milk to as low a temperature as is possible, dependent usually upon the temperature of the water supply. According to my experience if milk be clean it is not necessary to reduce it to a temperature lower than 60° F. during the first nine hours of its existence, by which time usually it has left the farm.

I have outlined what is necessary for the production of milk of satisfactory quality. Milk so produced will be found to meet the requirements of the present standard of "Grade A" milk, or, if it comes from a tubercle-free herd for "Grade A (tuberculin tested)" or for "Certified" if it be bottled on the farm. Anyone who sells milk that falls below Grade A standard is selling an article so damaged that it cannot be regarded as satisfactory. According to my calculations, if the producer disregards the necessary requirements (which he usually contrives with the distributor to fulfil) he saves about a halfpenny a gallon by omitting clean methods, and about a further twopenny a gallon by omitting to ensure that his herd is healthy.

I am satisfied that it is impossible at the present time for the majority of farmers to maintain tubercle-free herds for various reasons. As a result of the classification of milk that was inaugurated by the Ministry of Food during the war and which has been extended since by the Ministry of Health in co-operation with the Ministry of Agriculture, the number of tubercle-free herds in this country has been increased from two or three to upwards of one hundred and fifty, but it is not possible to deal with the question of the national milk supply upon the basis of anticipating that,

for many years to come, the bulk of our milk can be produced under such conditions. But the production of milk of decent cleanliness is practicable. If the producers of this country want to do it if their lenders are courageous enough to lend and to teach progress, the entire milk supply that is at present used for liquid consumption can soon be raised to the present Grade A standard. That is the standard that should be demanded by the public, and until the public is sufficiently educated, which at present it is not, it is the standard that should be required by all public health authorities or officials who come in contact with the milk supply in the course of their duties.

The question of how to deal with milk from non-tested herds so that it shall not contain any living tubercle bacilli is a very important one, and is outside the scope of this paper. It resolves itself into whether milk from herds that are not free from tuberculous animals shall be consumed raw or pasteurized. In the larger American and Canadian cities such milk must be pasteurized. Pasteurization may or may not have its disadvantages, but personally I should not offer milk to children that I did not know did not contain living tubercle bacilli. I am satisfied that all milk sold for consumption as liquid milk could be and should be at least of Grade A standard, whether it is to be consumed raw or pasteurized.

II—GEORGE P. MALE, M.R.C.V.S.,

Reading

THE POINT OF VIEW OF THE VETERINARY SURGEON. Pure milk may be defined as "the product derived from the normal udder of a healthy cow," and in dealing with this subject there are two factors to be considered: (1) contaminations that may take place after the milk leaves the cow from handling utensils, and accidental infections; (2) contaminations arising from unhealthy cows.

With regard to the first, great strides have been made in recent years to ascertain the exact nature of the bacterial infections, and how they arise, but I expect you will wish me to deal more particularly with the second class of impurities.

I should like to say, however, briefly, that the chief source of contamination is from the vessels in which the milk is placed, such as milk churns, pails, coolers, etc., and if careful washing and sterilization by steam is thoroughly carried out the bacterial count can be reduced to a minimum. A certain amount of contamination does occur from dirty udders and from the milker's hands, but not to the extent that is generally supposed. This can be prevented to a great extent by a proper system of drainage and construction of the byres, by clipping off the long hairs round the udder, and by washing, if necessary, or wiping with a clean cloth the udders before milking. It is not necessary to have elaborately built cowsheds for this purpose so long as attention to detail is ensured. I emphasize this because many people have the idea that vast sums must be spent on new buildings before they can hope to get pure milk and so do not attempt it.

A proper water-tight floor, with the right length of stall and guttering is quite adequate, if the cows are groomed, the udders washed, and all vessels that come in contact with the milk are properly sterilized. In regard to the last, I may say that good and comparatively cheap sterilizers can be obtained now which answer every purpose so that no producer need be deterred from trying to obtain pure milk owing to expense under the first head.

Contaminations arising from Unhealthy Cows

The solution of this problem is not quite so easy, although after nearly twenty years' experience I have not yet found it insuperable nor is it an impracticable proposition for any owner of cows. There are many diseased conditions which may affect the purity of the milk, but the most important one is tuberculosis.

The fact that bovine tuberculosis is communicable to man and that from 5,000 to 10,000 children die each year from tuberculosis, chiefly abdominal, derived from cow's milk, besides causing untold suffering in many other non-fatal

eases, makes it imperative that the milk must be freed from this contamination. It has been stated by eminent authorities that perhaps bovine tubercle bacilli taken in this way may produce some immunity to human tuberculosis, but unfortunately one cannot control the dose, and one could not say which child would be protected or which one would succumb to such administration, therefore it cannot be entertained for one moment.

Many methods have been advocated for freeing herds of tuberculosis, ranging from a diet rich in vitamins to the wholesale slaughter of all reacting animals with compensation by the State, but time will not permit me to do it with these in detail. I am, however, satisfied that the tuberculin test, if carefully employed, is the most helpful agent for the purpose, and with proper facilities for isolating reactors, and for the breeding and rearing of non-tuberculous young stock, it can be relied upon to obtain a healthy herd, or one in which the percentage of reactors is very small indeed, within a reasonable time.

Experiments are now being made to improve the method of testing, and just recently a valuable report was issued by the Tuberculin Committee of the Medical Research Council on an improved method of applying the intradermal test. Whether this will supersede the subcutaneous test or not I cannot say. It will have to be tested on large numbers of animals under field conditions first, but at any rate it will be very useful as a secondary test in doubtful cases. Any method which will simplify the test and make it less irksome to the operator and less expensive for the owner will be welcome, as the present regulations required by the Ministry of Health for the production of Grade A milk involve a great deal of exacting work and make it very difficult for many veterinary surgeons and owners to carry out on a large scale. To turn out on a winter's night at about 10 o'clock to go to some far away premises to test a number of cows with the aid of a lantern, then to take the temperatures again, commencing at 4 a.m., and so on every three hours to the eighteenth hour, is scarcely a picnic, but to do it sometimes six nights out of seven is a labour of love in which happily very few of you are privileged to participate.

The expense involved in the eradication of tuberculosis from a herd arises from two sources: (1) the cost of the test itself, and (2) the culling of the affected cows.

With regard to the first, veterinary surgeons are co-operating with the producers in reducing expenses to as low a level as possible, so it need not be seriously considered. The second expense depends upon the number of reactors. In some herds only 5 to 10 per cent react, while in others the percentage may rise to 50 or even 80, when it is a very serious matter and will have to be considered very carefully. That it is sound economics I will endeavour to prove for many reasons:

1 In badly affected herds the number of diseased cows often called "wasters" amounts to perhaps 10 or 15 per cent a year. I know of quite a number of herds of about 50 cows where the "wasters" have numbered 10 or more in a single year and if one takes the average value of a cow at only £30 it will mean £300 loss a year.

2 Cows suffering from tuberculosis are frequently ill, weak, have coughs, chills or pneumonia, there are often variations in the quantity of milk given, they suffer from enlarged glands in the throat with difficult and noisy breathing, udder troubles are frequent, and there is always an indefinable something which keeps them back, giving constant cause for anxiety, whereas in a tubercle-free herd the cows are rarely ill, and speaking from experience the assistance of a veterinary surgeon is hardly ever needed.

3 The average life of a tuberculous cow is considerably less than that of a healthy one.

4 It costs more to feed and keep in condition a diseased herd, tuberculosis being a wasting disease an affected animal requires more food to supply its needs.

5 If a pedigree herd it will be very difficult to sell an animal to foreign buyers, and a great many home buyers also demand the tuberculin test, and the value of a tuberculin animal will be about one half or one third that of a healthy one.

6 Sooner or later tubercle bacilli are sure to find their way into the milk. Then the owner will be obliged to take steps to find the offending cow or cows, and he may not be able to sell the milk until this has been done, also he may, under the Milk and Dairies Act 1915, soon be obliged to be fined very heavily and have his licence taken away, which makes it imperative that he should put his house in order.

7 There is always a ready sale at enhanced prices for young stock from healthy cows.

8 When sold to the butcher there will be less loss from carcasses seized by the meat inspector as unsound. The losses under this head all over the country must be enormous. The value of diseased tuberculous carcasses seized in Edinburgh market alone amounted to £5,000 in one year. Not only is this the case with cattle but also with pigs. In certain parts of Australia where the herds have been cleared of tubercle it was found that the number of pig carcasses with tuberculous diseased proportioned.
